

Modern C++ Programming

15. ADVANCED TOPICS

Federico Busato

University of Verona, Dept. of Computer Science
2021, v3.03

1 Move Semantic

- lvalues and rvalues references
- Move Semantic
- Compiler Implicitly Declared
- `std::move`

2 Universal Reference and Perfect Forwarding

- Universal Reference
- Reference Collapsing Rules
- Perfect Forwarding

3 Value Categories

4 Copy Elision and RVO

5 Type Deduction

- Pass-by-Reference
- Pass-by-Pointer
- Pass-by-Value

auto Deduction

6 `const` Correctness

7 C++ Idioms

- Rule of Zero/Three/Five
- Singleton
- PIMPL
- CRTP
- Template Virtual Functions

8 Smart pointers

- `std::unique_ptr`
- `std::shared_ptr`
- `std::weak_ptr`

9 Concurrency

- Thread Methods
- Mutex
- Atomic
- Task-based parallelism

Move Semantic

Move semantics refers in transferring ownership of resources from one object to another

Differently from *copy semantic*, *move semantic* does not duplicate the original resource

In C++ every expression is either an **rvalue** or an **lvalue**

- a **lvalue** (left) represents an expression that occupies some identifiable location in memory
- a **rvalue** (right) is an expression that does not represent an object occupying some identifiable location in memory

```
int x = 5;           // "x" is a lvalue, "5" is an rvalue  
int y = 10;          // "y" is a lvalue  
  
int z = (x * y);     // "z" is an lvalue, (x * y) is an rvalue
```

C++11 introduces a new kind of *reference* called **rvalue reference** `X&&`

- An **rvalue reference** only binds to an **rvalue**, that is a temporary
- An **lvalue reference** only binds to an **lvalue**
- A **const lvalue reference** binds to both **lvalue** and **rvalue**

```
int      x  = 5;           // "x" is an lvalue
int&     r1 = x;           // "r1" is an lvalue reference
// int&   r2 = 5;          // error, "5" is an rvalue
const int& cr = (x * y);   // "cr" is an const lvalue reference

int&&     rv = (x * y);    // "rv" is an rvalue
// int&&   rv1 = x;         // error, "x" is NOT an rvalue
```

```
struct A {};  
  
void f(A& a) {}           // lvalue reference  
  
void g(const A& a) {}     // const lvalue reference  
  
void h(A&& a) {}          // rvalue reference  
  
int main() {  
    A a;  
    f(a); // ok, f() can modify "a"  
    g(a); // ok, f() cannot modify "a"  
    // h(a); // compile error f() does not accept lvalues  
  
    // f(A{}); // compile error f() does not accept rvalues  
    g(A{}); // ok, f() cannot modify the object A{}  
    h(A{}); // ok, f() can modify the object A{}  
}
```

```
#include <algorithm>

class Array { // Array Wrapper
public:
    Array() = default;

    Array(int size) : _size{size}, _array{new int[size]} {}

    Array(const Array& obj) : _size{obj._size} {
        // EXPENSIVE COPY
        std::copy(obj._array, obj._array + _size, _array);
    }

    ~Array() { delete[] _array; }
private:
    int _size;
    int* _array;
};
```

```
#include <vector>

int main() {
    std::vector<Array> vector;
    vector.push_back( Array{1000} ); // expensive copy
}
```

Before C++11: `Array{1000}` is created, passed by const-reference, copied, and then destroyed

Note: `Array{1000}` is no more used outside `push_back`

After C++11: `Array{1000}` is created, and moved in `vector` (fast!)

Class prototype with support for *move semantic*:

```
class X {  
public:  
    X();                // default constructor  
  
    X(const X& obj);     // copy constructor  
  
    X(X&& obj);         // move constructor  
  
    X& operator=(const X& obj); // copy assign operator  
  
    X& operator=(X&& obj);   // move assign operator  
  
    ~X();               // destructor  
private:  
    Y _data;  
};
```

Move constructor semantic

```
X(X&& obj);
```

- (1) *Shallow copy* of `obj` data members (in contrast to deep copy)
- (2) *Release* any `obj` resources and reset all data members (pointer to `nullptr`, size to 0, etc.)

Move assignment semantic

```
X& operator=(X&& obj);
```

- (1) *Release* any resources of `this`
- (2) *Shallow copy* of `obj` data members (in contrast to deep copy)
- (3) *Release* any `obj` resources and reset all data members (pointer to `nullptr`, size to 0, etc.)
- (4) Return `*this`

Move constructor

```
Array(Array&& obj) {  
    _size      = obj._size;  // (1) shallow copy  
    _array     = obj._array; // (1) shallow copy  
    obj._size  = 0;          // (2) release obj (no more valid)  
    obj._array = nullptr;    // (2) release obj  
}
```

Move assignment

```
Array& operator=(Array&& obj) {  
    delete[] _array;    // (1) release this  
    _size = obj._size;  // (2) shallow copy  
    _array = obj._array; // (2) shallow copy  
    delete[] obj._array; // (3) release obj  
    obj._size = 0;      // (3) release obj  
    return *this;       // (4) return *this  
}
```

Special Members

compiler implicitly declares

user declares		default constructor	destructor	copy constructor	copy assignment	move constructor	move assignment
	Nothing	defaulted	defaulted	defaulted	defaulted	defaulted	defaulted
	Any constructor	not declared	defaulted	defaulted	defaulted	defaulted	defaulted
	default constructor	user declared	defaulted	defaulted	defaulted	defaulted	defaulted
	destructor	defaulted	user declared	defaulted	defaulted	not declared	not declared
	copy constructor	not declared	defaulted	user declared	defaulted	not declared	not declared
	copy assignment	defaulted	defaulted	defaulted	user declared	not declared	not declared
	move constructor	not declared	defaulted	deleted	deleted	user declared	not declared
	move assignment	defaulted	defaulted	deleted	deleted	not declared	user declared

C++11 provides the method `std::move` (`<utility>`) to indicate that an object may be “moved from”

It allows to efficient transfer resources from an object to another one

```
#include <vector>

int main() {
    std::vector<Array> vector;
    vector.push_back( Array{1000} );    // call move constructor
                                        // (C++11)

    Array arr{1000};
    vector.push_back( arr );            // call copy constructor
                                        // (also in C++11)

    vector.push_back( std::move(arr) ); // call move constructor
}
```

Universal Reference and Perfect Forwarding

The `&&` syntax has two different meanings depending on the context it is used

- **rvalue reference**
- Either **rvalue reference** or **lvalue reference**
(*universal reference*, cit. Scott Meyers)

“Universal references” (also called *forwarding references*) are **rvalues** that appear in a type-deducing context

```
void f1(int&& t) {} // rvalue reference

template<typename T>
void f2(T&& t) {}  // universal reference

int&& v1 = ...;    // rvalue reference
auto&& v2 = ...;   // universal reference
```

```
struct A {};  
void f1(A&& a) {} // rvalue only  
  
template<typename T>  
void f2(T&& t) {} // universal reference  
  
int main() {  
    A a;  
    f1(A{}); // ok  
    // f1(a); // compile error (only rvalue)  
    f2(A{}); // universal reference  
    f2(a);   // universal reference  
  
    A&& a2 = A{}; // ok  
    // A&& a3 = a; // compile error (only rvalue)  
    auto&& a4 = A{}; // universal reference  
    auto&& a5 = a;   // universal reference  
}
```

Universal Reference - Misleading Cases

```
template<typename T>
void f(const T&&) {}           // rvalue reference (const)

template<typename T>
void f(std::vector<T>&&) {}    // rvalue reference

const auto&& v = ...;         // const lvalue reference
```

Reference Collapsing Rules

Before C++11 (C++98, C++03), it was not allowed to take a reference to a reference (`A& &` causes a compile error)

C++11, by contrast, introduces the following **reference collapsing rules**:

```
template<typename T>
void f(T&) {} // compile error in C++98/03
               // (with gcc), no errors in C++11
int a = 3;    // (and clang with C++98/03)
f<int&>(a);
```

Type	Reference		Result
A&	&	→	A&
A&	&&	→	A&
A&&	&	→	A&
A&&	&&	→	A&&

Perfect Forwarding

Perfect forwarding allows preserving argument *value category* and `const/volatile` modifiers

`std::forward` (`<utility>`) forwards the argument to another function with the *value category* it had when passed to the calling function (*perfect forwarding*)

```
#include <utility> // std::forward
template<typename T> void f(T& t) { cout << "lvalue"; }
template<typename T> void f(T&& t) { cout << "rvalue"; }

template<typename T> void g1(T&& obj) { f(obj); } // call only f(T&)
template<typename T> void g2(T&& obj) { f(std::forward<T>(obj)); }

struct A{};
f ( A{10} ); // print "rvalue"
g1( A{10} ); // print "lvalue"!!
g2( A{10} ); // print "lvalue"
```

Value Categories

Taxonomy (simplified)

Every expression is either an **rvalue** or an **lvalue**

- An **lvalue** (*left* value of an assignment for historical reason or *locator* value) represents an expression that occupies an *identity*, namely a memory location (it has an address)
- **rvalues** (*right* value of an assignment) are defined by exclusion
- An **rvalue** is movable; an **lvalue** is not

glvalue (*generalized lvalue*) is an expression that has an identity

lvalue is a **glvalue** but it is not movable (it is not an **xvalue**).

An *named rvalue reference* is a **lvalue**

prvalue (*pure rvalue*) doesn't have identity, but is movable. It is an expression whose evaluation initializes an object or computes the value of an operand of an operator

xvalue (*eXpiring*) has an identity and it is movable. It is a **glvalue** that denotes an object whose resources can be reused. An *unnamed rvalue reference* is a **xvalue**

rvalue is movable. It is a **prvalue** or an **xvalue**

Examples

```
struct A {  
    int x;  
};  
  
void f(A&&) {}  
A&& g();  
//-----  
  
int a = 4;           // "a" is an lvalue, "4" is a prvalue  
f(A{4});             // "A{4}" is a prvalue  
  
A&& b = A{3};        // "A&& b" is a named rvalue reference → lvalue  
  
A c{4};  
f(std::move(c));     // "std::move(c)" is a xvalue  
f(A{}.x);            // "A{}.x" is a xvalue  
g();                 // "g()" is a xvalue
```

Copy Elision and RVO

Copy elision is a compiler optimization technique that eliminates unnecessary copying/moving of objects (it is defined in the C++ standard)

A compiler avoids omitting copy/move operations with the following optimizations:

- **RVO (Return Value Optimization)** means the compiler is allowed to avoid creating *temporary* objects for return values
- **NRVO (Named Return Value Optimization)** means the compiler is allowed to return an object (with automatic storage duration) without invokes copy/move constructors

Returning an object from a function is a *very expensive* operation without RVO/NVRO:

```
struct Obj {  
    Obj() = default;  
  
    Obj(const Obj&) { // non-trivial  
        cout << "copy constructor\n";  
    }  
};  
  
Obj f() { return Obj{}; } // first copy  
  
auto x1 = f();           // second copy (create "x")  
Obj x2{ f() };           // same situation (other two copies)
```

If provided, the compiler uses the *move constructor* instead of *copy constructor*

RVO Copy elision is always guarantee if the operand is a prvalue of the same class type and the *copy constructor* is trivial and non-deleted

```
struct Trivial {  
    Trivial()                = default;  
    Trivial(const Trivial&) = default;  
};  
  
// sigle instance  
Trivial f1() {  
    return Trivial{}; // Guarantee RVO  
}  
  
// distinct instances and run-time selection  
Trivial f2(bool b) {  
    return b ? Trivial{} : Trivial{}; // Guarantee RVO  
}
```

In C++17, *RVO Copy elision* is always guarantee if the operand is a prvalue of the same class type, even if the *copy constructor* is not trivial or deleted

```
struct S1 {  
    S1()          = default;  
    S1(const S1&) = delete; // deleted  
};  
  
struct S2 {  
    S2()          = default;  
    S2(const S2&) {}          // non-trivial  
};  
  
S1 f() { return S1{}; }  
S2 g() { return S2{}; }  
  
auto x1 = f(); // compile error in C++14  
auto x2 = g(); // RVO only in C++17
```

NVRO is not always guarantee even in C++17

```
Obj f1() {  
    Obj a;  
    return a; // most compilers apply NRVO  
}  
  
Obj f2(bool v) {  
    Obj a;  
    if (v)  
        return a; // copy/move constructor  
    return Obj{}; // RVO  
}  
  
Obj f3(bool v) {  
    Obj a, b;  
    return v ? a : b; // copy/move constructor  
}
```

```
Obj f4() {  
    Obj a;  
    return std::move(a); // force move constructor  
}  
  
Obj f5() {  
    static Obj a;  
    return a; // only copy constructor is possible  
}
```

Type Deduction

When you call a template function, you may omit any template argument that the compiler can determine or deduce (inferred) by the usage and context of that template function call [IBM]

- The compiler tries to deduce a template argument by comparing the type of the corresponding template parameter with the type of the argument used in the function call
- Similar to function default parameters, (any) template parameters can be deduced only if they are at end of the parameter list

Full Story: IBM Knowledge Center

Example

```
template<typename T>
int add1(T a, T b) { return a + b; }

template<typename T, typename R>
int add2(T a, R b) { return a + b; }

template<typename T, int B>
int add3(T a) { return a + B; }

template<int B, typename T>
int add4(T a) { return a + B; }

int main() {
    add1(1, 2);           // ok
    // add1(1, 2u);       // the compiler expects the same type
    add2(1, 2u);          // ok (add2 is more generic)
    add3<int, 2>(1);       // "int" cannot be deduced
    add4<2>(1);           // ok
}
```

Type Deduction - Pass-by-Reference

Type deduction with references

```
template<typename T>
void f(T& a) {}

template<typename T>
void g(const T& a) {}

int main() {
    int      x = 3;
    int&     y = x;
    const int& z = x;
    f(x);    // T: int
    f(y);    // T: int
    f(z);    // T: const int // <-- !! it works...but it does not
    g(x);    // T: int      //      for "f(int& a)"!!
    g(y);    // T: int      //      (only non-const references)
    g(z);    // T: int      // <-- note the difference
}
```

Type deduction with pointers

```
template<typename T>
void f(T* a) {}

template<typename T>
void g(const T* a) {}

int main() {
    int*      x = nullptr;
    const int* y = nullptr;
    auto      z = nullptr;
    f(x);      // T: int
    f(y);      // T: const int
    // f(z);    // compile error!! z: "nullptr_t != T*"
    g(x);      // T: int
    g(y);      // T: int    <-- note the difference
}
```

```
template<typename T>
void f(const T* a) {} // pointer to const-values

template<typename T>
void g(T* const a) {} // const pointer

int main() {
    int*          x = nullptr;
    const int*    y = nullptr;
    int* const    z = nullptr;
    const int* const w = nullptr;
    f(x);        // T: int
    f(y);        // T: int
    f(z);        // T: int
    // g(x);      // compile error!! objects pointed are not constant
    // g(y);      // the same (the pointer itself is constant)
    g(z);        // T: int
    g(w);        // T: const int
}
```

Type deduction with values

```
template<typename T>
void f(T a) {}

template<typename T>
void g(const T a) {}

int main() {
    int      x = 2;
    const int y = 3;
    const int& z = y;
    f(x);    // T: int
    f(y);    // T: int!! (drop const)
    f(z);    // T: int!! (drop const&)
    g(x);    // T: int
    g(y);    // T: int
    g(z);    // T: int!! (drop reference)
}
```

```
template<typename T>
void f(T a) {}

int main() {
    int*      x = nullptr;
    const int* y = nullptr;
    int* const z = x;
    f(x);    // T = int*
    f(y);    // T = int* !! (const drop)
    f(z);    // T = int* const
}
```

Type Deduction - Array

Type deduction with arrays

```
template<typename T, int N>
void f(T (&array)[N]) {}    // type and size deduced

template<typename T>
void g(T array) {}

int main() {
    int      x[3] = {};
    const int y[3] = {};
    f(x);    // T: int, N: 3
    f(y);    // T: const int, N: 3
    g(x);    // T: int*
    g(y);    // T: const int*
}
```

```
template<typename T>
void add(T a, T b) {}

template<typename T, typename R>
void add(T a, R b) {}

template<typename T>
void add(T a, char b) {}

int main() {
    add(2, 3.0f);           // call add(T, R)
    // add(2, 3);           // error!! ambiguous match
    add<int>(2, 3);          // call add(T, T)
    add<int, int>(2, 3);     // call add(T, R)
    add(2, 'b');            // call add(T, char) -> nearest match
}
```

```
template<typename T, int N>
void f(T (&array)[N]) {}

template<typename T>
void f(T* array) {}

// template<typename T>
// void f(T array) {} // ambiguous

int main() {
    int x[3];
    f(x); // call f(T*) not f(T(&)[3]) !!
}
```

auto Deduction

- `auto x =` copy by-value/by-const value
- `auto& x =` copy by-reference/by-const-reference
- `auto* x =` copy by-pointer/by-const-pointer
- `auto&& x =` copy by-universal reference
- `decltype(auto) x =` automatic type deduction

```
int          f1(int& x) { return x; }
int&         f2(int& x) { return x; }
auto         f3(int& x) { return x; }
decltype(auto) f4(int& x) { return x; }

int  v  = 3;
int  x1 = f1(v);
int& x2 = f2(v);
// int& x3 = f3(v);
int& x4 = f4(v);
```

const Correctness

const correctness refers to guarantee object/variable const consistency throughout its lifetime and ensuring safety from unintentional modifications

References:

- Isocpp: `const-correctness`
- GotW: `Const-Correctness`
- Abseil: `Meaningful 'const' in Function Declarations`
- `const` is a contract
- `Why const Doesn't Make C Code Faster`
- `Constant Optimization?`

- `const` entities do not change their values at run-time. This does not imply that they are evaluated at compile-time
- `const T*` is different from `T* const`. The first case means *“the content does not change”*, while the later *“the value of the pointer does not change”*
- Pass *by-const-value* and *by-value* parameters imply the *same* function signature
- Return *by-const-value* and *by-value* have different meaning
- `const_cast` can *break* const-correctness

`const` and member function:

- `const` member functions do not change the internal status of an object
- `mutable` fields can be modified by a `const` member function (they should not change the external view)

`const` and code optimization:

- `const` keyword purpose is for correctness (*type safety*) not for performance
- `const` may provide performance advantages in a few cases, e.g. non-trivial copy semantic

Function Declarations Example

```
void f(int);  
void f(const int); // the declaration is exactly the same of  
                  // "void f(int)!!"  
  
void f(int*);  
void f(const int*); // different declaration  
  
void f(int&);  
void f(const int&); // different declaration
```

```
int          f();  
// const int f(); // compile error conflicting declaration
```

const Return Example

```
const int const_value = 3;

const int& f2() { return const_value; }
// int&      f1() { return const_value; } // WRONG
int      f3() { return const_value; }      // ok
```

```
struct A {
    void f()      { cout << "non-const"; }
    void f() const { cout << "const";     }
};
```

```
const A getA() { return A{}; }
```

```
auto a = getA(); // "a" is a copy
a.f();          // print "non-const"
```

```
getA().f();      // print "const"
```

struct Example

```
struct A {           // struct A_const { // equal to "const A"
    int* ptr;         //      int* const ptr;
    int  value;       //      const int  value;
};                   // };

void f(A a) {
    a.value = 3;
    a.ptr[0] = 3;
}

void g(const A a) { // the same with g(const A&)
//  a.value = 3; // compile error
    a.ptr[0] = 3; // "const" does not apply to "ptr" content!!
}

A a{new int[10]};
f(a);
g(a);
```

Member Functions Example

```
struct A {  
    int value = 0;  
  
    int&      f1() { return value; }  
    const int& f2() { return value; }  
  
    // int&      f3() const { return value; } // WRONG  
    const int& f4() const { return value; }  
  
    int      f5() const { return value; } // ok  
    const int f6() const { return value; }  
};
```

C++ Idioms

Rule of Zero

The **Rule of Zero** is a rule of thumb for C++

Utilize the *value semantics* of existing types to avoid having to implement *custom* copy and move operations

Note: many classes (such as `std` classes) manage resources themselves and should not implement copy/move constructor and assignment operator

```
class X {  
public:  
    X(...); // constructor  
           // NO need to define copy/move semantic  
private:  
    std::vector<int>    v; // instead raw allocation  
    std::unique_ptr<int> p; // instead raw allocation  
};  
                        // see smart pointer
```

Rule of Three

The **Rule of Three** is a rule of thumb for C++(03)

If your class needs any of

- a copy constructor `X(const X&)`
- an assignment operator `X& operator=(const X&)`
- or a destructor `~X()`

defined explicitly, then it is likely to need all three of them

Some resources cannot or should not be copied. In this case, they should be declared as deleted

```
X(const X&) = delete  
X& operator=(const X&) = delete
```

Rule of Five

The **Rule of Five** is a rule of thumb for C++11

If your class needs any of

- a copy constructor `X(const X&)`
- a move constructor `X(X&&)`
- an assignment operator `X& operator=(const X&)`
- an assignment operator `X& operator=(X&&)`
- or a destructor `~X()`

defined explicitly, then it is likely to need all five of them

Singleton

Singleton is a software design pattern that restricts the instantiation of a class to one and only one object

A common application is for logging

```
class Singleton {
public:
    static Singleton& get_instance() { // note "static"
        static Singleton instance { ..init.. } ;
        return instance;    // destroyed at the end of the program
    }
                            // initiliazied at first use

    Singleton(const& Singleton)      = delete;
    void operator=(const& Singleton) = delete;
private:
    T _data;

    Singleton( ..args.. ) { // used in the initialization
        ...
    }
}
```

PIMPL (Opaque Pointer)

Pointer to IMPLementation (PIMPL) idiom allow removing compilation dependencies on internal class implementations and improve compile times

header.hpp

```
class A {           // the class A is responsible to allocate
public:             // and deallocate Impl* ptr
    void f() {
        ptr->f();
    }
private:
    class Impl;     // forward declaration
    Impl* ptr;      // opaque pointer
};
```

source.cpp (Impl actual implementation)

```
class A::Impl {
public:
    void f() {
        ..do something..
    }
};
```

The **Curiously Recurring Template Pattern (CRTP)** is an idiom in which a class `X` derives from a class template instantiation using `X` itself as template argument

A common application is *static polymorphism*

```
template <class T>
struct Base {
    void my_method() {
        static_cast<T*>(this)->implementation();
    }
};

class Derived : public Base<Derived> {
    // void my_method() is inherited
    void my_method_impl() { ... } // private method
};
```

```
#include <iostream>

template <typename T>
struct Writer {
    void write(const char* str) {
        static_cast<const T*>(this)->write_impl(str);
    }
};

class CerrWriter : public Writer<CerrWriter> {
    void write_impl(const char* str) { std::cerr << str; }
};

class CoutWriter : public Writer<CoutWriter> {
    void write_impl(const char* str) { std::cout << str; }
};

CoutWriter x;
CerrWriter y;
x.write("abc");
y.write("abc");
```

```
template <typename T>
void f(Writer<T>& writer) {
    writer.write("abc");
}
```

```
CoutWriter x;
CerrWriter y;
f(x);
f(y);
```

Virtual functions cannot have template arguments, but they can be emulated by using the following pattern

```
class Base {  
public:  
    template<typename T>  
    void method(T t);    // here we want to emulate a virtual method  
}
```

```
class Base {  
public:  
    template<typename T>  
    void method(T t) {  
        v_method(t);    // call the actual implementation  
    }  
private:  
    virtual void v_method(int t)    = 0; // v_method is valid only  
    virtual void v_method(double t) = 0; // for "int" and "double"  
};
```

Actual implementations for derived class `A` and `B`

```
class AImpl : public Base {
protected:
    template<typename T>
    void t_method(T t) { // template "method()" implementation for A
        std::cout << "A " << t << std::endl;
    }
};

class BImpl : public Base {
protected:
    template<typename T>
    void t_method(T t) { // template "method()" implementation for B
        std::cout << "B " << t << std::endl;
    }
};
```

```
template<class Impl>
class DerivedWrapper : public Impl {
private:
    void v_method(int t) {
        Impl::t_method(t);
    }
    void v_method(double t) {
        Impl::t_method(t);
    } // call the base method
};

using A = DerivedWrapper<AImpl>;
using B = DerivedWrapper<BImpl>;
```

```
int main(int argc, char* argv[]) {
    A a;
    B b;
    Base* base = nullptr;

    base = &a;
    base->method(1);    // print "A 1"
    base->method(2.0);  // print "A 2.0"

    base = &b;
    base->method(1);    // print "B 1"
    base->method(2.0);  // print "B 2.0"
}
```

method() calls v_method() (pure virtual method of Base)
v_method() calls t_method() (actual implementation)

Smart pointers

Smart Pointers

Smart pointer is a pointer-like type with some additional functionality, e.g. *automatic memory deallocation* (when the pointer is no longer in use, the memory it points to is deallocated), reference counting, etc.

C++11 provides three smart pointer types:

- `std::unique_ptr`
- `std::shared_ptr`
- `std::weak_ptr`

Smart pointers prevent most situations of memory leaks by making the memory deallocation automatic

Full Story: embeddedartistry.com

Smart Pointers Benefits

- If a smart pointer goes *out-of-scope*, the appropriate method to release resources is called automatically. The memory is not left dangling
- Smart pointers will automatically be set to `nullptr` if not initialized or when memory has been released
- `std::shared_ptr` provides automatic reference count
- If a special `delete` function needs to be called, it will be specified in the pointer type and declaration, and will automatically be called on delete

std::unique_ptr is used to manage any dynamically allocated object that is not shared by multiple objects

```
#include <iostream>
#include <memory>
struct A {
    A() { std::cout << "Constructor\n"; } // called when A()
    ~A() { std::cout << "Destructor\n"; } // called when u_ptr1,
};                                     // u_ptr2 are out-of-scope

int main() {
    auto raw_ptr = new A();
    std::unique_ptr<A> u_ptr1(new A());
    std::unique_ptr<A> u_ptr2(raw_ptr);
    // std::unique_ptr<A> u_ptr3(raw_ptr); // no error, but wrong!!
                                     // (same pointer)
    // u_ptr1 = &raw_ptr; // compile error (unique pointer)
    // u_ptr1 = u_ptr2;   // compile error (unique pointer)
    u_ptr1 = std::move(u_ptr2); // delete u_ptr1;
    // u_ptr1 = u_ptr2;
    // u_ptr2 = nullptr
}
```

std::unique_ptr methods

- `get()` returns the underlying pointer
- `operator*` `operator->` dereferences pointer to the managed object
- `operator[]` provides indexed access to the stored array (if it supports random access iterator)
- `release()` returns a pointer to the managed object and releases the ownership
- `reset(ptr)` replaces the managed object with `ptr`

Utility method: `std::make_unique<T>()` creates a unique pointer of a class `T` that manages a new object

```
#include <iostream>
#include <memory>

struct A {
    int value;
};

int main() {
    std::unique_ptr<A> u_ptr1(new A());
    u_ptr1->value;      // dereferencing
    (*u_ptr1).value;    // dereferencing

    auto u_ptr2 = std::make_unique<A>(); // create a new unique pointer

    u_ptr1.reset(new A());           // reset
    auto raw_ptr = u_ptr1.release(); // release
    delete[] raw_ptr;

    std::unique_ptr<A[]> u_ptr3(new A[10]);
    auto& obj = u_ptr3[3];           // access
}
```

Implements a custom deleter

```
#include <iostream>
#include <memory>

struct A {
    int value;
};

int main() {
    auto DeleteLambda = [](A* x) {
        std::cout << "delete" << std::endl;
        delete x;
    };

    std::unique_ptr<A, decltype(DeleteLambda)>
        x(new A(), DeleteLambda);
} // print "delete"
```

std::shared_ptr is the pointer type to be used for memory that can be owned by multiple resources at one time

std::shared_ptr maintains a reference count of pointer objects. Data managed by std::shared_ptr is only freed when there are no remaining objects pointing to the data

```
#include <iostream>
#include <memory>
struct A {
    int value;
};
int main() {
    std::shared_ptr<A> sh_ptr1(new A());
    std::shared_ptr<A> sh_ptr2(sh_ptr1);
    std::shared_ptr<A> sh_ptr3(new A());
    sh_ptr3 = nullptr; // allowed, the underlying pointer is deallocated
                    // sh_ptr3 : zero references
    sh_ptr2 = sh_ptr1; // allowed // sh_ptr1, sh_ptr2: two references
    sh_ptr2 = std::move(sh_ptr1); // allowed // sh_ptr1: zero references
                                // sh_ptr2: one references
}
```

`std::shared_ptr` methods

- `get()` returns the underlying pointer
- `operator*` `operator->` dereferences pointer to the managed object
- `use_count()` returns the number of objects referring to the same managed object
- `reset(ptr)` replaces the managed object with `ptr`

Utility method: `std::make_shared()` creates a shared pointer that manages a new object

```
#include <iostream>
#include <memory>
struct A {
    int value;
};

int main() {
    std::shared_ptr<A> sh_ptr1(new A());
    auto sh_ptr2 = std::make_shared<A>(); // std::make_shared
    std::cout << sh_ptr1.use_count(); // print 1

    sh_ptr1 = sh_ptr2; // copy
    // std::shared_ptr<A> sh_ptr2(sh_ptr1); // copy (constructor)
    std::cout << sh_ptr1.use_count(); // print 2
    std::cout << sh_ptr2.use_count(); // print 2

    auto raw_ptr = sh_ptr1.get(); // get
    sh_ptr1.reset(new A()); // reset

    (*sh_ptr1).value = 3; // dereferencing
    sh_ptr1->value = 2; // dereferencing
}
```

A `std::weak_ptr` is simply a `std::shared_ptr` that is allowed to dangle (pointer not deallocated)

```
#include <iostream>
#include <memory>

struct A {
    int value;
};

int main() {
    auto ptr = new A();
    std::weak_ptr<A> w_ptr(ptr);
    std::shared_ptr<A> sh_ptr(new A());

    sh_ptr = nullptr;
    // delete sh_ptr.get(); // double free or corruption

    w_ptr = nullptr;
    delete w_ptr; // ok valid
}
```

It must be converted to `std::shared_ptr` in order to access the referenced object

`std::weak_ptr` methods

- `use_count()` returns the number of objects referring to the same managed object
- `reset(ptr)` replaces the managed object with `ptr`
- `expired()` checks whether the referenced object was already deleted (`true`, `false`)
- `lock()` creates a `std::shared_ptr` that manages the referenced object

```
#include <iostream>
#include <memory>
struct A {
    int value;
};
int main() {
    auto sh_ptr1 = std::make_shared<A>();

    std::cout << sh_ptr1.use_count(); // print 1
    std::weak_ptr<A> w_ptr = sh_ptr1;
    std::cout << w_ptr.use_count();   // print 1

    auto sh_ptr2 = w_ptr.lock();
    std::cout << sh_ptr2.use_count(); // print 2 (sh_ptr1 + sh_ptr2)

    sh_ptr1 = nullptr;
    std::cout << w_ptr.expired();     // print false

    sh_ptr2 = nullptr;
    std::cout << w_ptr.expired();     // print true
}
```

Concurrency

Overview

C++11 introduces the **Concurrency** library to simplify managing OS threads

```
#include <iostream>
#include <thread>

void f() {
    std::cout << "first thread" << std::endl;
}

int main(){
    std::thread th(f);
    th.join();           // stop the main thread until "th" complete
}
```

How to compile:

```
$g++ -std=c++11 main.cpp -pthread
```

Example

```
#include <iostream>
#include <thread>
#include <vector>

void f(int id) {
    std::cout << "thread " << id << std::endl;
}

int main() {
    std::vector<std::thread> thread_vect; // thread vector
    for (int i = 0; i < 10; i++)
        thread_vect.push_back( std::thread(&f, i) );

    for (auto& th : thread_vect)
        th.join();

    thread_vect.clear();
    for (int i = 0; i < 10; i++) { // thread + lambda expression
        thread_vect.push_back(
            std::thread( [](){ std::cout << "thread\n"; } ) );
    }
}
```

Library methods:

- `std::this_thread::get_id()` returns the thread id
- `std::thread::sleep_for(sleep_duration)`
Blocks the execution of the current thread for at least the specified `sleep_duration`
- `std::thread::hardware_concurrency()` returns the number of concurrent threads supported by the implementation

Thread object methods:

- `get_id()` returns the thread id
- `join()` waits for a thread to finish its execution
- `detach()` permits the thread to execute independently from the thread handle

```
#include <chrono>    // the following program should (not deterministic)
#include <iostream>  // produces the output:
#include <thread>     //   child thread exit
                    //   main thread exit

int main() {
    using namespace std::chrono_literals;
    std::cout << std::this_thread::get_id();
    std::cout << std::thread::hardware_concurrency(); // e.g. print 6

    auto lambda = []() {
        std::this_thread::sleep_for(1s); // t2
        std::cout << "child thread exit\n";
    };
    std::thread child(lambda);
    child.detach(); // without detach(), child must join() the
                  // main thread (run-time error otherwise)
    std::this_thread::sleep_for(2s);    // t1
    std::cout << "main thread exit\n";
}

// if t1 < t2 the should program prints:
//   main thread exit
```

Parameters Passing

Parameters passing *by-value* or *by-pointer* to a thread function works in the same way of a standard function. *Pass-by-reference* requires a special wrapper (`std::ref` , `std::cref`) to avoid wrong behaviors

```
#include <iostream>
#include <thread>
void f(int& a, const int& b) {
    a = 7;
    const_cast<int&>(b) = 8;
}
int main() {
    int a = 1, b = 2;
    std::thread th1(f, a, b);                // wrong!!!
    std::cout << a << ", " << b << std::endl; // print 1, 2!!

    std::thread th2(f, std::ref(a), std::cref(b)); // correct
    std::cout << a << ", " << b << std::endl;     // print 7, 8!!
    th1.join(); th2.join();
}
```

The following code produces (in general) a value < 1000 :

```
#include <chrono>
#include <iostream>
#include <thread>
#include <vector>

void f(int& value) {
    for (int i = 0; i < 10; i++) {
        value++;
        std::this_thread::sleep_for(std::chrono::milliseconds(10));
    }
}

int main() {
    int value = 0;
    std::vector<std::thread> th_vect;
    for (int i = 0; i < 100; i++)
        th_vect.push_back( std::thread(f, std::ref(value)) );

    for (auto& it : th_vect)
        it.join();
    std::cout << value;
}
```

C++11 provide the `mutex` class as synchronization primitive to protect shared data from being simultaneously accessed by multiple threads

`mutex` methods:

- `lock()` locks the *mutex*, blocks if the *mutex* is not available
- `try_lock()` tries to lock the *mutex*, returns if the *mutex* is not available
- `unlock()` unlocks the *mutex*

More advanced mutex can be found here: en.cppreference.com/w/cpp/thread

C++ includes three mutex wrappers to provide safe copyable/movable objects:

- `lock_guard` (C++11) implements a strictly scope-based mutex ownership wrapper
- `unique_lock` (C++11) implements movable mutex ownership wrapper
- `shared_lock` (C++14) implements movable shared mutex ownership wrapper

```
#include <chrono>
#include <iostream>
#include <thread>
#include <vector>

void f(int& value, std::mutex& m) {
    for (int i = 0; i < 10; i++) {
        m.lock();
        value++;    // other threads must wait
        m.unlock();
        std::this_thread::sleep_for(std::chrono::milliseconds(10));
    }
}

int main() {
    std::mutex m;
    int value = 0;
    std::vector<std::thread> th_vect;
    for (int i = 0; i < 100; i++)
        th_vect.push_back( std::thread(f, std::ref(value), std::ref(m)) );
    for (auto& it : th_vect)
        it.join();
    std::cout << value;
}
```

Atomic

`std::atomic` (C++11) template class defines an atomic type that are implemented with lock-free operations (much faster than locks)

```
#include <atomic>
... // include also: chrono, iostream, thread, vector

void f(std::atomic<int>& value) {
    for (int i = 0; i < 10; i++) {
        value++;
        std::this_thread::sleep_for(std::chrono::milliseconds(10));
    }
}

int main() {
    std::atomic<int> value(0);
    std::vector<std::thread> th_vect;
    for (int i = 0; i < 100; i++)
        th_vect.push_back( std::thread(f, std::ref(value)) );
    for (auto& it : th_vect)
        it.join();
    std::cout << value;    // print 1000
}
```

The `future` library provides facilities to obtain values that are returned and to catch exceptions that are thrown by *asynchronous* tasks

Asynchronous call: `std::future async(function, args...)`
runs a function asynchronously (potentially in a new thread)
and returns a `std::future` object that will hold the result

`std::future` methods:

- `T get()` returns the result
- `wait()` waits for the result to become available

`async()` can be called with two launch policies for a task executed:

- `std::launch::async` a new thread is launched to execute the task asynchronously
- `std::launch::deferred` the task is executed on the calling thread the first time its result is requested (lazy evaluation)

```
#include <iostream>
#include <vector>
#include <algorithm>
#include <numeric>
#include <future>
template <typename RandomIt>
int parallel_sum(RandomIt beg, RandomIt end) {
    auto len = end - beg;
    if (len < 1000)    // base case
        return std::accumulate(beg, end, 0);

    RandomIt mid = beg + len / 2;
    auto handle = std::async(std::launch::async, // right side
                             parallel_sum<RandomIt>, mid, end);
    int sum = parallel_sum(beg, mid);    // left side
    return sum + handle.get();    // left + right
}
int main() {
    std::vector<int> v(10000, 1); // init all to 1
    std::cout << "The sum is " << parallel_sum(v.begin(), v.end());
}
```
