2021, v3.06

## 1 Function Template

- Overview
- Template Parameters
- Template Parameter - Default Value
- Specialization
- Overloading
- auto Deduction

## 2 Compile-Time Utilities

- `static_assert`
- `decltype` Keyword
- `using` Keyword

## **3** Type Traits

- Overview
- Type Traits Library
- Type Manipulation
- Type Relation and Transformation

## **4** Template Parameters

- Overview
- Special Cases

# Function Template

---

# Template Overview

## Template

A **template** is a mechanism for generic programming to provide a "*schema*" (or *placeholders*) to represent the structure of an entity

In C++, *templates* are a compile-time functionality to represent:

- A family of **functions**
- A family of **classes**
- A family of **variables** C++14

Templates are a way to make code *more reusable* and *faster*

*negative sides*: hard to read, cryptic error messages, larger binary size, and higher compile time

**The problem:** We want to define a function to handle different types

```
int add(int a, int b) {  
    return a + b;  
}  
  
float add(float a, float b) { // overloading  
    return a + b;  
}  
  
char    add(char a, char b)      { ... } // overloading  
ClassX  add(ClassX a, ClassX b) { ... } // overloading
```

- Redundant code!!
- How many functions we have to write!?
- If the user introduces a new type we have to write another function!!

## Function Templates

**Function templates** are special functions that can operate with *generic* types (independent of any particular type)

Allow to create a function template whose functionality can be adapted to more than one type or class without repeating the entire code for each type

```
template<typename T> // or template<class T>
T add(T a, T b) {
    return a + b;
}

int    c1 = add(3, 4);           // c1 = 7
float  c2 = add(3.0f, 4.0f);     // c2 = 7.0f
int    c3 = add<int>(3.0f, 4.0f); // c3 = 7 (int forced)
```

# Templates: Benefits and Drawbacks

## Benefits

- **Generic Programming:** Less code and reusable. Reduce *redundancy*, better *maintainability* and *flexibility*
- **Performance.** Computation can be done at compile-time

## Drawbacks

- **Readability.** With respect to C++, the syntax and idioms of templates are *esoteric* compared to conventional C++ programming, and templates can be very difficult to understand [wikipedia]
- **Compile Time.** Templates are implicitly instantiated for every different parameters

# Template Parameters

```
template<typename T>
```

`typename T` is a **template parameter**

In common cases, a **template parameter** can be:

- *generic type*: `typename`
- *non-type template parameters*
  - *integral type*: `int`, `char`, etc. (but not floating point)
  - *enumerator*: `enum`, *enumerator class*: `enum class`

### int parameter

```
template<int A, int B>
int add_int() {
    return A + B; // sum is computed at compile-time
}                // e.g. add_int<3, 4>();
```

### enum parameter

```
enum class Enum { Left, Right };

template<Enum Z>
int add_enum(int a, int b) {
    return (Z == Enum::Left) ? a + b : a;
}    // e.g. add_enum<Enum::Left>(3, 4);
```

- Ceiling division

```
template<int DIV, typename T>
T ceil_div(T value) {
    return (value + DIV - 1) / DIV;
}
// e.g. ceil_div<5>(11); // returns 3
```

- Rounded division

```
template<int DIV, typename T>
T round_div(T value) {
    return (value + DIV / 2) / DIV;
}
// e.g. round_div<5>(11); // returns 2 (2.2)
```

Since DIV is known at compile-time, the compiler can heavily optimize the division (almost for every numbers, not just for power of two)

# Code Generation

The compiler generates a specific **function implementation** for every template parameter instance

```
template<typename T>
T add(T a, T b) {
    return a + b;
}

add(3, 4);           // generates: int    add(int, int)
add(3.0f, 4.0f);    // generates: float add(float, float)
add(2, 6);           // already generated
// other instances are not generated
// e.g. char add(char, char)
```

**C++11** Template parameters can have default values  
(only at the end of the parameter list)

```
// template<int A = 3, int B>    // compile error
template<int A = 3>
int print1() {
    cout << A;
}

print1<2>();    // print 2
print1<>();     // print 3 (default)
print1();      // print 3 (default)
```

## Template parameters may have no name

```
void f() {}

template<typename = void>
void g() {}

int main() {
    g(); // generated
}
```

`f()` is always generated in the final code

`g()` is generated in the final code only if it is called

**C++11** Unlike function parameters, template parameters can be initialized by previous values

```
template<int A, int B = A + 3>
void f() {
    cout << B;
}

template<typename T, int S = sizeof(T)>
void g(T) {
    cout << S;
}

f<3>();    // B is 6
g(3);     // S is 4
```

## Specialization

**Specialization** refers to the concrete implementation for a specific combination of template parameters

### The problem:

```
template<typename T>
T compare(T a, T b) {
    return a < b;
}
```

The direct comparison between two floating-point values is dangerous due to rounding errors

**Solution:** Template specialization

```
template<>
float compare<float>(float a, float b) {
    return ...    // floating point relative error implementation
}                // see "Basic I" lecture
```

Full Specialization: *Function* templates can be specialized only if **ALL** template arguments are specialized

# Function Template - Overloading

## Template Functions can be *overloaded*

```
template<typename T>
T add(T a, T b) {
    return a + b;
} // e.g add(3, 4);

template<typename T>
T add(T a, T b, T c) { // different number of parameters
    return a + b + c;
} // e.g add(3, 4, 5);
```

## Also templates themselves can be *overloaded*

```
template<int C, typename T>
T add(T a, T b) { // it is not in conflict with
    return a + b + C; // T add(T a, T b)
} // "C" is part of the signature
```

# auto Deduction

C++17 introduces automatic deduction of *non-type* template parameters with the `auto` keyword

```
template<int X, int Y>
```

```
void f() {}
```

```
template<auto X, auto Y>
```

```
void g() {}
```

```
f<2u, 2u>();    // X: int, Y: int
```

```
g<2, 3>();      // X: int,      Y: int
```

```
g<2u, 2u>();    // X: unsigned, Y: unsigned
```

```
g<2, 3u>();     // X: int,      Y: unsigned
```

# Compile-Time Utilities

---

## C++11 `static_assert` is used to test a software assertion at compile-time

If the static assertion fails, the program does not compile

```
static_assert(2 + 2 == 4, "test1"); // ok, it compiles
static_assert(2 + 2 == 5, "test2"); // compile error
static_assert(sizeof(void*) * 8 == 64, "test3");
// depends on the OS (32/64-bit)
```

```
template<typename T, typename R>
void f(T, R) {
    static_assert(sizeof(T) == sizeof(R), "test4");
}

f<int, unsigned>(); // ok, it compiles
// f<int, char>(); // compile error
```

C++11 `decltype` is a keyword used to get the type of an *entity* or an *expression*

- `decltype` never executes, it only evaluates at compile-time

```
int      x = 3;
int&     y = x;
const int z = 4;
int array[2];

decltype(x);      // int
decltype(2 + 3.0); // double
decltype(y);      // int&
decltype(z);      // const int
decltype(array);  // int[2]
```

```
bool f(int) { return true; }

struct A {
    int x;
};
int x = 3;
const A a;

decltype(x);      // int
decltype((x));    // int&

decltype(f);      // bool
decltype((f));    // bool (*)(int)

decltype(a.x);    // int
decltype((a.x));  // const int
```

## C++11

```
template<typename T, typename R>  
decltype(T{} + R{}) add(T x, R y) {  
    return x + y;  
}
```

```
unsigned v1 = add(1, 2u);  
double   v2 = add(1.5, 2u);
```

## C++14

```
template<typename T, typename R>  
auto add(T x, R y) {  
    return x + y;  
}
```

# using Keyword

## using keyword (C++11)

`using` introduces *alias templates* (synonyms)

- `using` is an enhanced version of `typedef`
- `using` keyword is useful to simplify complex template expression
- `using` keyword allows defining partial and full specialization

```
template<typename T, typename R>
struct A {};

template<typename T>
using Alias = A<T, int>;           // called "Alias Template"

using IntAlias = A<int, int>;

Alias<char> a; // A<char, int>
IntAlias    b; // A<int, int>
```

# Type Traits

---

## Introspection

**Introspection** is the ability to inspect a type and retrieve its various qualities

## Reflection

**Reflection** is the ability of a computer program to examine, introspect, and modify its own structure and behavior at runtime

**C++ provides compile-time reflection and introspection capabilities through type traits**

## Type traits (C++11)

**Type traits** defines a compile-time interface to query or modify the properties of types

The problem:

```
template<typename T>
T floor_div(T a, T b) {
    return a / b;
}

floor_div(7, 2);      // returns 3 (int)
floor_div(71, 21);    // returns 3 (long int)
floor_div(7.0, 3.0); // ??? it compiles, but the result is
                     // not what we expect
```

Two alternatives: (1) Specialize (2) Type Traits + `static_assert`

If we want to **prevent floating-point division at compile-time** a first solution consists in specialize for all “integral” types

```
template<typename T>
T floor_div(T a, T b); // declaration (error for other types)

template<>
char floor_div<char>(char a, char b) { // specialization
    return a / b;
}

template<>
int floor_div<int>(int a, int b) { // specialization
    return a / b;
}

...unsigned char
...short
...
```

**Very redundant!!**

The best solution is to use **type traits**

```
#include <type_traits>          // <-- std type traits library

template<typename T>
T floor_div(T a, T b) {
    static_assert(std::is_integral<T>::value,
                  "floor_div accepts only integral types");
    return a / b;
}
```

`std::is_integral<T>` is a struct with a boolean field `value`

It is true if T is a `bool`, `char`, `short`, `int`, `long`,  
`long long`, false otherwise

- `is_integral` checks for an integral type (bool, char, unsigned char, short, unsigned short, int, long, etc.)
- `is_floating_point` checks for a floating-point type (float, double)
- `is_arithmetic` checks for a integral or floating-point type
- `is_signed` checks for a signed type (float, int, etc.)
- `is_unsigned` checks for an unsigned type (unsigned T, bool, etc.)
- `is_enum` checks for an enumerator type (enum, enum class)

- `is_void` checks for (void)
- `is_pointer` checks for a pointer (T\*)
- `is_nullptr` checks for a (nullptr) C++14
- `is_reference` checks for a reference (T&)
- `is_array` checks for an array (T (&)[N])
- `is_function` checks for a function type
- `is_const` checks if a type is const

- `is_class` checks for a class type (struct, class, not enum class)
- `is_empty` checks for empty class types (struct A {})
- `is_abstract` checks for a class with at least one pure virtual function
- `is_polymorphic` checks for a class with at least one virtual function
- `is_final` checks for a class that cannot be extended

## Example (const Deduction)

```
#include <type_traits>

template<typename T>
void f(T x) { cout << std::is_const<T>::value; }

template<typename T>
void g(T& x) { cout << std::is_const<T>::value; }

template<typename T>
void h(T& x) {
    cout << std::is_const<T>::value;
    x = nullptr; // ok, it compiles for T: (const int)*
}

const int a = 3;
f(a); // print false, "const" drop in pass by-value
g(a); // print true
const int* b = nullptr;
h(b); // print false!! T: (const int)*
```

**Type traits** allows also to manipulate types by using the **type** field (can be used also in the return type of a function)

Example: convert `int` to `unsigned`

```
#include <type_traits>

using T = int;
T x = -3; // int

using R = typename std::make_unsigned<int>::type;
R y = 5; // unsigned
```

In general, type traits (or other *templated* structures) depends on a template (*dependent name*) (int in the previous example). In these cases, the compiler needs to know if `::type` is a type or a static member in advance

The keyword `typename` placed before the *structure template* solves this ambiguous

e.g. `typename std::make_unsigned<T>::type` is a type

The expression can be combined with `using` or `typedef` to improve the readability

e.g. `using R = typename std::make_unsigned<int>::type;`

## Signed and Unsigned types:

- `make_signed` makes a type signed
- `make_unsigned` makes a type unsigned

## Pointers and References:

- `remove_pointer` remove pointer ( $T^* \rightarrow T$ )
- `remove_lvalue_reference` remove reference ( $T\& \rightarrow T$ )
- `add_pointer` add pointer ( $T \rightarrow T^*$ )
- `add_lvalue_reference` add reference ( $T \rightarrow T\&$ )

## Const-Volatile Specifiers:

- `remove_const` remove const ( $\text{const } T \rightarrow T$ )
- `remove_volatile` remove volatile ( $\text{volatile } T \rightarrow T$ )
- `remove_cv` remove const and volatile
- `add_const` add const

```
#include <type_traits>

template<typename T>
void f(T ptr) {
    using R = typename std::remove_pointer<T>::type;
    R x = ptr[0]; // char
}

template<typename T>
void g(T x) {
    using R = typename std::add_const<T>::type;
    R y = 3;
    // y = 4;    // compile error
}

char a[] = "abc";
int b = 3;
f(a); // T: char*
g(b); // T: int
```

# Type Relation and Transformation

## Type relation:

- `is_same<T, R>` check if T and R are the same type
- `is_base_of<T, R>` check if T is base of R
- `is_convertible<T, R>` check if T can be converted to R

## Type Transformation:

- `common_type<T, R>` returns the common type between T and R
- `conditional<pred, T, R>` returns T if pred is true, R otherwise
- `decay<T>` returns the same type as function pass-by-value

## Example

```
#include <type_traits>

template<typename T, typename R>
T add(T a, R b) {
    static_assert(std::is_same<T, R>::value,
                  "T and R must be the same")
    return a + b;
}

struct A {}
struct B : A {}

add(1, 2);           // ok
// add(1, 2.0);     // compile error
std::is_base<A, B>::value; // true
std::is_base<A, A>::value; // true
std::is_convertible<int, float>::value; // true
```

## std::common\_type Example

```
#include <type_traits>

template<typename T, typename R>
typename std::common_type<R, T>::type // <-- return type
add(T a, R b) {
    return a + b;
}

add(3, 4.0f); // .. but we don't know the type of the result

// we can use decltype to derive the result type of
// a generic expression
using result_t = decltype(add(3, 4.0f));
result_t x = add(3, 4.0f);
```

## std::conditional Example

```
#include <type_traits>

template<typename T, typename R>
void f(T a, R b) {
    const bool pred = sizeof(T) > sizeof(R);
    using S = typename std::conditional<pred, T, R>::type;
    S result = a + b;
}

f(2, 'a'); // S: int
f(2, 2ull); // S: unsigned long long
```

# Type Traits in C++14/17

C++14 and C++17 provide utilities to improve the readability of type traits

```
#include <type_traits>

std::is_signed_v<int>;          // std::is_signed<int>::value
std::is_same_v<int, float>;    // std::same<int, float>::value

std::make_unsigned_t<int>;
// instead of: typename std::make_unsigned<int>::type

std::conditional_t<true, int, float>;
// instead of: typename std::conditional<true, int, float>::type
}
```

# Template Parameters

---

# Template Parameters

Template parameters can be:

- *integral type* (int, char, etc) (not floating point)
- *enumerator, enumerator class*
- *generic type* (**can be anything**)

But also:

- *function*
- *reference* to global static function or object
- *pointer* to global static function or object
- *pointer to member type* cannot be used directly, but the function can be specialized
- `nullptr_t`

C++20 allows floating-point types and classes

# Generic Type Example

## Pass multiple values and floating-point types

```
// template<float V>    // compiler error
// void print() {      // not valid

template<typename T> // generic typename
void print() {
    cout << T::x << ", " << T::y;
//  cout << T::z;    // compiler error
}                    // "z" is not a member of Multi

struct Multi {
    static const      int    x = 1;
    static constexpr float y = 2.0f;
};

print<Multi>();    // print 2.0, 3.0
```

## Array and pointer

```
#include <iostream>

template<int* ptr>    // pointer
void g() {
    std::cout << ptr[0];
}

template<int (&array)[3]> // reference
void f() {
    std::cout << array[0];
}

int array[] = {2, 3, 4}; // global

int main() {
    f<array>(); // print 2
    g<array>(); // print 2
}
```

## Class member

```
struct A {
    int x    = 5;
    int y[3] = {4, 2, 3};
};

template<int A::*z>    // pointer to
void h1() {}           // member type

template<int (A::*z)[3]> // pointer to
void h2() {}           // member type

int main() {
    h1<&A::x>(); // print 5
    h2<&A::y>(); // print 4
}
```

## Function

```
template<int (*)(int, int)> // <-- signature of "f"
int apply1(int a, int b) {
    return g(a, b);
}

int f(int a, int b) {
    return a + b;
}

template<decltype(f)> // alternative syntax
void apply2(int a, int b) {
    return g(a, b);
}

int main() {
    apply1<f>(2, 3); // return 5
    apply2<f>(2, 3); // return 5
}
```
