Modern C++ Programming

3. Basic Concepts II

Federico Busato

University of Verona, Dept. of Computer Science 2020, v3.07

Table of Context

- 1 Enumerators
- 2 struct, union, and Bitfield
- 3 using, decltype, and auto
- **4** Math Operators
- **5** Statements and Control Flow
 - if Statement
 - for Loop
 - switch
 - goto

Enumerators

Enumerated Types

Enumerator

An **enumerator** (enum) is a data type that groups a set of named integral constants

```
enum color_t { BLACK, BLUE, GREEN = 2 };

color_t color = BLUE;
cout << (color == BLACK); // print false</pre>
```

The problem:

Enumerated Types (Strongly Typed)

enum class

C++11 introduces a *type safe* enumerator enum class (scoped enum) data type that are not implicitly convertible to int

```
enum class Color { BLACK, BLUE, GREEN = 2 };
enum class Fruit { APPLE, CHERRY };
Color color = Color::BLUE;
Fruit fruit = Fruit::APPLE;
// cout << (color == fruit); // compile error</pre>
// we are trying to match colors with fruits
// BUT, they are different things entirely
// int a = Color::GREEN; // compile error
```

enum class can be compared

```
enum class Color { RED = 1, GREEN = 2, BLUE = 3 };
cout << (Color::RED < Color::GREEN); // print true</pre>
```

enum class does <u>not</u> support other operations

```
enum color_t { RED = 1, GREEN = 2, BLUE = 3 };
enum class Color { RED = 1, GREEN = 2, BLUE = 3 };
int v = RED + GREEN; // ok
// int v = Color::RED + Color::GREEN; // compile error
```

• The size of enum class can be set

```
#include <cstdint>
enum class Color : int8_t { RED = 1, GREEN = 2, BLUE = 3 };
```

enum class can be explicitly converted

```
int a = (int) Color::GREEN; // ok
```

enum class should be always initialized

```
enum class Color { RED = 1, GREEN = 2, BLUE = 3 };
Color my_color; // "my_color" may be 0!!
```

enum class can contain alias

```
enum class Device { PC = 0, COMPUTER = 0, PRINTER = 1 };
```

• enum class is automatically enumerated

```
enum class Color { RED, GREEN = -1, BLUE, BLACK }; // (0) (-1) (0) (1) Color::RED == Color::BLUE; // true
```

■ C++17 Cast from *out-of-range values* to **enum class** leads to undefined behavior

```
enum Color { RED = 0, GREEN = 1, BLUE = 2 };
int main() {
   Color value = (int) 3; // undefined behavior
}
```

■ C++17 enum class supports direct-list-initialization

C++20 allows introducing the enumerator identifiers into the local scope

```
enum class Color { RED, GREEN, BLUE };

switch (x) {
   using enum Color; // C++20
   case RED:
   case GREEN:
   case BLUE:
}
```

Bitfield

struct, union, and

A structure struct allows aggregating different variables into a single unit

```
struct A {
   int x;
   char y;
   float z;
};
```

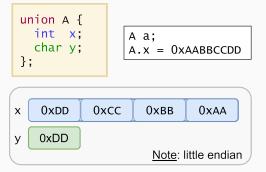

C++20 introduces designated initializer list

```
A a1{1, 0, 2}; // a.x == 1, a.y == 0, a.z == 2
A a2{.x = 1, .z = 2}; // designated initializer list
void f(A a) {}
f({.x = 1, .z = 2}) // designated initializer list
```

Union

A union is a special data type that allows to store different data types in the same memory location

- The union is only as big as necessary to hold its largest data member
- The union is a kind of "overlapping" storage

```
union A {
    int x;
    char y;
}; // sizeof(A): 4

A a;
a.x = 1023; // bits: 00..000001111111111
a.y = 0; // bits: 00..00000100000000
cout << a.x; // print 512 + 256 = 768</pre>
```

NOTE: Little-Endian encoding maps the bytes of a value in memory in the reverse order. y maps to the last byte of x

C++17 introduces std::variant to represent a type-safe union

Bitfield

A **bitfield** is a variable of a structure with a predefined bit width. A bitfield can hold bits instead bytes

```
struct S1 {
   int b1 : 10; // range [0, 1023]
   int b2 : 10; // range [0, 1023]
   int b3 : 8; // range [0, 255]
}; // sizeof(S1): 4 bytes
struct S2 {
   int b1 : 10;
   int : 0; // reset: force the next field
   int b2 : 10; // to start at bit 32
}; // sizeof(S1): 8 bytes
```

using, decltype, and auto

using and decltype

 C++11 The using keyword has the same semantics of typedef specifier (alias-declaration), but with a better syntax

```
typedef int distance_t; // equal to:
using distance_t = int;
```

 C++11 The decltype keyword captures the type of an object or an expression

C++11 The auto keyword specifies that the type of the variable will be automatically deduced by the compiler (from its initializer)

```
auto a = 1 + 2;  // 1 is int, 2 is int, 1 + 2 is int!
//    -> 'a' is "int"
auto b = 1 + 2.0; // 1 is int, 2.0 is double. 1 + 2.0 is double
//    -> 'b' is "double"
```

auto can be very useful for maintainability

```
for (auto i = k; i < size; i++)
...</pre>
```

On the other hand, it may make the code less readable if excessively used because of type hiding

Example: auto x = 0; in general makes no sense (x is int)

auto (as well as decltype) can be used for both function input
and output types

```
void f(auto x) {}
auto g(int x) { return x * 2; }

f(3);
f(3.0);
int x = g(3);
```

Math Operators

Precedence	Operator	Description	Associativity
1	a++ a	Suffix/postfix increment and decrement	Left-to-right
2	++aa	Prefix increment and decrement	Right-to-left
3	a*b a/b a%b	Multiplication, division, and remainder	Left-to-right
4	a+b a-b	Addition and subtraction	Left-to-right
5	« »	Bitwise left shift and right shift	Left-to-right
6	< <= > >=	Relational operators	Left-to-right
7	== !=	Equality operators	Left-to-right
8	&	Bitwise AND	Left-to-right
9	^	Bitwise XOR	Left-to-right
10		Bitwise OR	Left-to-right
11	&&	Logical AND	Left-to-right
12		Logical OR	Left-to-right

In general:

- Unary operators have <u>higher</u> precedence than binary operators
- Standard math operators (+, *, etc.) have <u>higher</u>
 precedence than comparison, bitwise, and logic operators
- Comparison operators have <u>higher</u> precedence than bitwise and logic operators
- Bitwise operators have <u>higher</u> precedence than logic operators

Full table

en.cppreference.com/w/cpp/language/operator_precedence

Examples:

Important: sometimes parenthesis can make expression worldly... but they can help!

Undefined Behavior

Expressions with undefined (implementation-defined) behavior:

```
int i = 0:
i = ++i + 2; // until C++11: undefined behavior
                 // since C++11: i = 3
i = 0;
i = i++ + 2; // until C++17: undefined behavior
                 // since C++17: i = 3
f(i = 2, i = 1); // until C++17: undefined behavior
                 // since C++17: i = 2
i = 0:
a[i] = i++; // until C++17: undefined behavior
                 // since C++17: a[1] = 1
f(++i, ++i); // undefined behavior
i = ++i + i++;  // undefined behavior
n = ++i + i; // undefined behavior
```

Statements and **Control Flow**

Assignment and Ternary Operator

Assignment special cases:

```
int a;
int b = a = 3; // (a = 3) return value 3
if (b = 4)  // it is not an error, but BAD programming
```

■ *Structure Binding* declaration: C++17

```
struct A {
    int x = 1;
    int y = 2;
} a;

auto [x1, y1] = a;
cout << x1 << " " << y1;</pre>
```

Ternary operator:

```
<cond> ? <expression1> : <expression2>
<expression1> and <expression2> must return a value of the same type
```

```
int value = (a == b) ? a : (b == c ? b : 3); // nested
```

if Statement

Short-circuiting:

```
if (<true expression> || array[-1] == 0)
... // no error!! even though index is -1
    // left-to-right evaluation
```

■ C++17 if statement with *initializer*:

```
void f(int x, int y) {
   if (int ret = x + y; ret < 10)
      cout << "a";
}</pre>
```

It aims at simplifying complex statement before the condition evaluation. Available also for switch statements

Loops

C++ provides three kinds of loop:

for

```
for ([init]; [cond]; [increment]) {
    ...
}
```

To use when number of iterations is known

while

```
while (cond) {
    ...
}
```

To use when number of iterations is not known

• do while

```
do {
...
} while (cond);
```

To use when number of iterations is not known, but there is at least one iteration

for Loop

■ C++ allows "in loop" definitions:

```
for (int i = 0, k = 0; i < 10; i++, k += 2)
...</pre>
```

Infinite loop:

```
for (;;) // also while(true);
...
```

Jump statements (break, continue, return):

```
for (int i = 0; i < 10; i++) {
   if (<condition>)
        break;  // exit from the loop
   if (<condition>)
        continue; // continue with a new iteration and exec. i++
   return;  // exit from the function
}
```

C++11 introduces the **range-based for loop** to simplify the verbosity of traditional **for** loop constructs. They are equivalent to the **for** loop operating over a range of values, but more **safe**

The range-based for loop avoids the user to specify start, end, and increment of the loop

Range-based for loop can be applied in three cases:

- Fixed-size array int array[3], "abcd"
- Branch Initializer List {1, 2, 3}
- Any object with begin() and end() methods

C++17 extends the concepts of **range-based loop** for *structure binding*

```
struct A {
    int x;
    int y;
};

A array[10] = { {1,2}, {5,6}, {7,1} };
for (auto [x1, y1] : array)
    cout << x1 << "," << y1 << " "; // print: 1,2 5,6 7,1</pre>
```

C++20 Range-based loop with initializer

```
for (int i = 0; auto x : {'A', 'B', 'C'})
  cout << i++ << ":" << x; // print: 1:A 2:B 3:C</pre>
```

C++ switch can be defined over int, char, enum class, enum, etc.

```
char x = ...
int y;
switch (x) {
    case 'a': y = 1; break;
    default: return -1;
}
return y;
```

Switch scope:

Fallthrough:

C++17 [[fallthrough]] attribute

C++20 introduces switch with initializer

```
switch (int i = 0; x) {
  case 2: i += 1;
  case 3: i += 2;
  default: return i;
}
```

When goto could be useful:

```
bool flag = true;
for (int i = 0; i < N && flag; i++) {
    for (int j = 0; j < M && flag; j++) {
        if (<condition>)
            flag = false;
    }
}
```

become:

```
for (int i = 0; i < N; i++) {
    for (int j = 0; j < M; j++) {
        if (<condition>)
            goto LABEL;
    }
}
```

Best solution:

```
bool my_function(int M, int M) {
    for (int i = 0; i < N; i++) {
        for (int j = 0; j < M; j++) {
            if (<condition>)
                 return false;
        }
    }
    return true;
}
```
