Modern C++ Programming

5. Basic Concepts IV Memory Management

Federico Busato

Heap and Stack

- Stack Memory
- new, delete
- Non-Allocating Placement Allocation ★
- Non-Throwing Allocation ★
- Memory Leak

2 Initialization

- Variable Initialization
- Uniform Initialization
- Fixed-Size Array Initialization
- Structure Initialization
- Dynamic Memory Initialization

3 Pointers and References

- Pointer Operations
- Address-of operator &
- Reference

4 Constants, Literals, const, constexpr, consteval,

constinit

- Constants and Literals
- const
- constexpr
- consteval
- constinit
- if constexpr
- std::is_constant_evaluated()
- if consteval

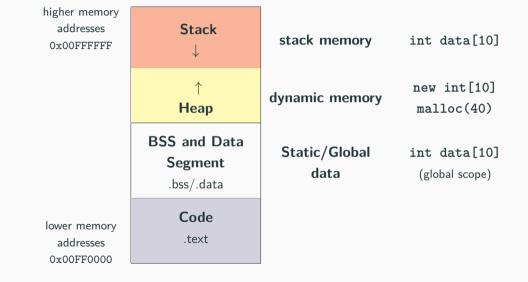

- **5** volatile **Keyword** ★
- **6** Explicit Type Conversion
 - static_cast, const_cast, reinterpret_cast
 - Type Punning
- 7 sizeof Operator

Heap and Stack

Parenthesis and Brackets

- $\{\}$ braces, informally "curly brackets"
- [] brackets, informally "square brackets"
- () parenthesis, informally "round brackets"
- <> angle brackets

Process Address Space

Data and BSS Segment

Data/BSS (Block Started by Symbol) segments are larger than stack memory (max $\approx 1 \text{GB}$ in general) but slower

Stack and Heap Memory Overview

Thread View

	Stack	Неар
Memory Organization	Contiguous (LIFO)	Contiguous within an allocation, Fragmented between allocations (relies on virtual memory)
Max size	Small (8MB on Linux, 1MB on Windows)	Whole system memory
If exceed	Program crash at function entry (hard to debug)	Exception or nullptr
Allocation	Compile-time	Run-time
Locality	High	Low

Shared among threads

9/81

Each thread has its own stack

Stack Memory

A local variable is either in the stack memory or CPU registers

```
int x = 3; // not on the stack (data segment)
struct A {
   int k; // depends on where the instance of A is
};
int main() {
   int y = 3;  // on stack
   char z[] = "abc"; // on stack
           // on stack (also k)
   A a:
   void* ptr = malloc(4): // variable "ptr" is on the stack
```

The organization of the stack memory enables much higher performance. On the other hand, this memory space is limited!!

Stack Memory Data

Types of data stored in the stack:

Local variables Variable in a local scope

Function arguments Data passed from caller to a function

Return addresses Data passed from a function to a caller

Compiler temporaries Compiler specific instructions

Interrupt contexts

Stack Memory

Every object which resides in the stack is not valid outside his scope!!

```
int* f() {
    int array[3] = {1, 2, 3};
    return array;
}
int* ptr = f();
cout << ptr[0]; // Illegal memory access!! $\mathref{L}$</pre>
```

```
void g(bool x) {
   const char* str = "abc";
   if (x) {
      char xyz[] = "xyz";
      str = xyz;
   }
   cout << str; // if "x" is true, then Illegal memory access!! \( \)
}</pre>
```

Heap Memory - new, delete Keywords

new, delete

new/new[] and delete/delete[] are C++ keywords that perform dynamic
memory allocation/deallocation, and object construction/destruction at runtime

malloc and free are C functions and they <u>only</u> allocate and free *memory blocks* (expressed in bytes)

new, delete Advantages

- Language keywords, not functions → safer
- Return type: new returns exact data type, while malloc() returns void*
- Failure: new throws an exception, while malloc() returns a NULL pointer → it
 cannot be ignored, zero-size allocations do not need special code
- Allocation size: The number of bytes is calculated by the compiler with the new keyword, while the user must take care of manually calculate the size for malloc()
- Initialization: new can be used to initialize besides allocate
- Polymorphism: objects with virtual functions must be allocated with new to initialize the virtual table pointer

14/81

Dynamic Memory Allocation

Allocate a single element

```
int* value = (int*) malloc(sizeof(int)); // C
int* value = new int; // C++
```

Allocate N elements

```
int* array = (int*) malloc(N * sizeof(int)); // C
int* array = new int[N]; // C++
```

Allocate N structures

```
MyStruct* array = (MyStruct*) malloc(N * sizeof(MyStruct)); // C
MyStruct* array = new MyStruct[N]; // C++
```

Allocate and zero-initialize N elements

```
int* array = (int*) calloc(N, sizeof(int)); // C
int* array = new int[N](); // C++
15/81
```

Dynamic Memory Deallocation

Deallocate a single element

```
int* value = (int*) malloc(sizeof(int)); // C
free(value);
int* value = new int; // C++
delete value;
```

Deallocate N elements

```
int* value = (int*) malloc(N * sizeof(int)); // C
free(value);
int* value = new int[N]; // C++
delete[] value;
```

Allocation/Deallocation Properties

Fundamental rules:

- Each object allocated with malloc() must be deallocated with free()
- Each object allocated with new must be deallocated with delete
- Each object allocated with new[] must be deallocated with delete[]
- malloc(), new, new[] never produce NULL pointer in the success case, except for zero-size allocations (implementation-defined)
- free(), delete, and delete[] applied to NULL / nullptr pointers do not
 produce errors

Mixing ${\tt new}$, ${\tt new[]}$, malloc with something different from their counterparts leads to undefined behavior

Easy on the stack - dimensions known at compile-time:

```
int A[3][4]; // C/C++ uses row-major order: move on row elements, then columns
```

Dynamic Memory 2D allocation/deallocation - dimensions known at run-time:

Dynamic memory 2D allocation/deallocation C++11:

Non-Allocating Placement ★

A **non-allocating placement** (ptr) type allows to explicitly specify the memory location (previously allocated) of individual objects

```
// STACK MEMORY
char buffer[8];
int* x = new (buffer) int;
short* y = new (x + 1) short[2];
// no need to deallocate x, y
```

```
// HEAP MEMORY
unsigned* buffer2 = new unsigned[2];
double* z = new (buffer2) double;
delete[] buffer2; // ok
// delete[] z; // ok, but bad practice
```

Non-Allocating Placement and Objects ★ ~>

Placement allocation of *non-trivial objects* requires to explicitly call the object destructor as the runtime is not able to detect when the object is out-of-scope

```
struct A {
      ~A() { cout << "destructor"; }
};

char buffer[10];
auto x = new (buffer) A();

// delete x; // runtime error 'x' is not a valid heap memory pointer
x->~A(); // print "destructor"
```

Non-Throwing Allocation *

The new operator allows a non-throwing allocation by passing the std::nothrow object. It returns a NULL pointer instead of throwing std::bad_alloc exception if the memory allocation fails

```
int* array = new (std::nothrow) int[very_large_size];
```

note: new can return NULL pointer even if the allocated size is 0

std::nothrow doesn't mean that the allocated object(s) cannot throw an exception
itself

```
struct A {
    A() { throw std::runtime_error{}; }
};

A* array = new (std::nothrow) A; // throw std::runtime_error
```

Memory Leak

Memory Leak

A **memory leak** is a dynamically allocated entity in the heap memory that is no longer used by the program, but still maintained overall its execution

Problems:

- Illegal memory accesses → segmentation fault/wrong results
- Undefined values a their propagation → segmentation fault/wrong results
- Additional memory consumption (potential segmentation fault)

```
int main() {
    int* array = new int[10];
    array = nullptr; // memory leak!!
} // the memory can no longer be deallocated!!
```

Note: the memory leaks are especially difficult to detect in complex code and when objects are widely used $^{23/81}$

Dynamic Memory Allocation and OS

A program does not directly allocate memory itself but it asks for a chuck of memory to the OS. The OS provides the memory at the granularity of *memory pages* (virtual memory), e.g. 4KB on Linux

Implication: out-of-bound accesses do not always lead to segmentation fault (lucky case). The worst case is an execution with undefined behavior

```
int* x = new int;
int num_iters = 4096 / sizeof(int); // 4 KB

for (int i = 0; i < num_iters; i++)
    x[i] = 1; // ok, no segmentation fault</pre>
```

Initialization

Variable Initialization

C++03:

```
int a1;
               // default initialization (undefined value)
int a2(2);
               // direct (or value) initialization
int a3(0);
               // direct (or value) initialization (zero-initialization)
// int a4(); // a4 is a function
int a5 = 2;  // copy initialization
int a6 = 2u;  // copy initialization (+ implicit conversion)
int a7 = int(2); // copy initialization
int a8 = int(); // copy initialization (zero-initialization)
int a9 = {2}; // copy list initialization
```

Uniform Initialization

C++11 **Uniform Initialization** syntax, also called *brace-initialization* or *braced-init-list*, allows to initialize different entities (variables, objects, structures, etc.) in a <u>consistent</u> way:

```
int b1{2};  // direct list (or value) initialization
int b2{};  // direct list (or value) initialization (zero-initialization)

int b3 = int{};  // copy initialization (zero-initialization)

int b4 = int{4};  // copy initialization

int b5 = {};  // copy list initialization (zero-initialization)
```

Brace Initialization Advantages

The **uniform initialization** can be also used to *safely* convert arithmetic types, preventing implicit *narrowing*, i.e potential value loss. The syntax is also more concise than modern casts

```
int b4 = -1; // ok
int b5{-1}; // ok
unsigned b6 = -1; // ok
//unsigned b7{-1}; // compile error

float f1{10e30}; // ok
float f2 = 10e40; // ok, "inf" value
//float f3{10e40}; // compile error
```

Fixed-Size Array Initialization

One dimension:

```
int a[3] = {1, 2, 3}; // explicit size
int b[] = {1, 2, 3}; // implicit size
char c[] = "abcd"; // implicit size
int d[3] = {1, 2}; // d[2] = 0 -> zero/default value

int e[4] = {0}; // all values are initialized to 0
int f[3] = {}; // all values are initialized to 0 (C++11)
int g[3] {}; // all values are initialized to 0 (C++11)
```

Two dimensions:

```
struct S {
   unsigned x;
   unsigned y;
};
S s1; // default initialization, x,y undefined values
S s2 = {}; // copy list initialization, x,y zero/default-initialization
S s3 = \{1, 2\}; // copy list initialization, x=1, y=2
S s4 = {1}; // copy list initialization, x=1, y zero/default-initialization
//S s5(3, 5): // compiler error, constructor not found
S f() {
   S = \{1, 2\}: // verbose
   return s6:
```

```
struct S {
    unsigned x;
    unsigned v;
    void* ptr;
};
S s1{}; // direct list (or value) initialization
               // x.y.ptr zero/default-initialization
S s2{1, 2}: // direct list (or value) initialization
               // x=1, y=2, ptr zero/default-initialization
// S s3{1, -2}: // compile error, narrowing conversion
S f() { return {3, 2}; } // non-verbose
```

Non-Static Data Member Initialization (NSDMI), also called *brace or equal initialization*:

```
struct S {
    unsigned x = 3; // equal initialization
    unsigned y = 2; // equal initialization
};
struct S1 {
    unsigned x {3}; // brace initialization
};
S s1; // call default constructor (x=3, y=2)
S s2{}; // call default constructor (x=3, y=2)
S s3{1, 4}; // set x=1, y=4
```

C++20 introduces designated initializer list

```
struct A {
    int x, y, z;
};
A a1{1, 2, 3};
// is the same of
A a2{.x = 1, .y = 2, .z = 3}; // designated initializer list
```

Designated initializer list can be very useful for improving code readability

Structure Binding

Structure Binding declaration C++17 binds the specified names to elements of initializer:

```
struct A {
   int x = 1;
   int y = 2;
} a;
A f() { return A{4. 5}: }
// Case (1): struct
auto [x1, y1] = a; //x1=1, y1=2
auto [x2, y2] = f(); // x2=4, y2=5
// Case (2): raw arrays
int b[2] = \{1,2\};
auto [x3, y3] = b; // x3=1, y3=2
// Case (3): tuples
auto [x4, y4] = std::tuple < float, int > {3.0f, 2};
```

Dynamic Memory Initialization

```
C++03:
```

C++11:

References

Pointers and

Pointer

A pointer T* is a value referring to a location in memory

Pointer Dereferencing

Pointer **dereferencing** (*ptr) means obtaining the value stored in at the location refereed to the pointer

Subscript Operator []

The subscript operator (ptr[]) allows accessing to the pointer element at a given position

The **type of a pointer** (e.g. void*) is an *unsigned* integer of 32-bit/64-bit depending on the underlying architecture

- lt only supports the operators +, -, ++, --, comparisons
 ==, !=, <, <=, >, >=, subscript [], and dereferencing *
- A pointer can be explicitly converted to an integer type

```
void* x;
size_t y = (size_t) x; // ok (explicit conversion)
// size_t y = x; // compile error (implicit conversion)
```

Pointer Conversion

- Any pointer type can be implicitly converted to void*
- Non- void pointers must be explicitly converted
- static_cast † is not allowed for pointer conversion for safety reasons, except for void*

Dereferencing:

```
int* ptr1 = new int;
*ptr1 = 4;    // dereferencing (assignment)
int a = *ptr1; // dereferencing (get value)
```

Array subscript:

```
int* ptr2 = new int[10];
ptr2[2] = 3;
int var = ptr2[4];
```

Common error:

```
int *ptr1, ptr2; // one pointer and one integer!!
int *ptr1, *ptr2; // ok, two pointers
```

Subscript operator meaning:

```
ptr[i] is equal to *(ptr + i)
```

Note: subscript operator accepts also negative values

Pointer arithmetic rule:

```
address(ptr + i) = address(ptr) + (sizeof(T) * i)
```

where T is the type of elements pointed by ptr

int arr[3] =
$$\{4,5,6\}$$
value address

0x11 & \\
0x1 & \\
0x1$$

Address-of operator &

The address-of operator (&) returns the address of a variable

To not confuse with **Reference syntax:** T& var = ...

Wild and Dangling Pointers

Wild pointer:

```
int main() {
   int* ptr;  // wild pointer: Where will this pointer points?
   ...  // solution: always initialize a pointer
}
```

Dangling pointer:

```
int main() {
   int* array = new int[10];
   delete[] array; // ok -> "array" now is a dangling pointer
   delete[] array; // double free or corruption!!
   // program aborted, the value of "array" is not null
}
```

note:

```
int* array = new int[10];
delete[] array; // ok -> "array" now is a dangling pointer
array = nullptr; // no more dagling pointer
delete[] array: // ok. no side effect
```

void Pointer - Generic Pointer

Instead of declaring different types of pointer variable it is possible to declare single pointer variable which can act as any pointer types

- void* can be compared
- Any pointer type can be implicitly converted to void*
- Other operations are unsafe because the compiler does not know what kind of object is really pointed to

```
cout << (sizeof(void*) == sizeof(int*)); // print true

int array[] = { 2, 3, 4 };
void* ptr = array; // implicit conversion
cout << *array; // print 2
// *ptr; // compile error
// ptr + 2; // compile error</pre>
43/81
```

Reference

A variable **reference** T& is an **alias**, namely another name for an already existing variable. Both variable and variable reference can be applied to refer the value of the variable

- A pointer has its own memory address and size on the stack, reference shares the same memory address (with the original variable)
- The compiler <u>can</u> internally implement references as *pointers*, but treats them in a very different way

References are safer than pointers:

- References <u>cannot have NULL</u> value. You must always be able to assume that a reference is connected to a legitimate storage
- References <u>cannot be changed</u>. Once a reference is initialized to an object, it cannot be changed to refer to another object
 (Pointers can be pointed to another object at any time)
- References must be <u>initialized</u> when they are created (Pointers can be initialized at any time)

Reference - Examples

Reference syntax: T& var = ...

```
//int& a; // compile error no initialization
//int \& b = 3: // compile error "3" is not a variable
int c = 2;
int& d = c; // reference. ok valid initialization
int& e = d; // ok. the reference of a reference is a reference
d++; // increment
e++; // increment
cout << c: // print 4
int a = 3;
int* b = &a; // pointer
int* c = &a; // pointer
b++; // change the value of the pointer 'b'
*c++; // change the value of 'a' (a = 4)
int& d = a; // reference
                                                                            46/81
d++; // change the value of 'a' (a = 5)
```

Reference vs. pointer arguments:

```
void f(int* value) {} // value may be a nullptr
void g(int& value) {} // value is never a nullptr
int a = 3;
f(\&a): // ok
f(0); // dangerous but it works!! (but not with other numbers)
//f(a): // compile error "a" is not a pointer
g(a); // ok
//q(3); // compile error "3" is not a reference of something
//q(&a); // compile error "&a" is not a reference
```

References can be use to indicate fixed size arrays:

```
void f(int (&array)[3]) { // accepts only arrays of size 3
    cout << sizeof(array);</pre>
void g(int array[]) {
    cout << sizeof(array); // any surprise?</pre>
int A[3], B[4];
int* C = A:
f(A): // ok
// f(B); // compile error B has size 4
// f(C); // compile error C is a pointer
g(A); // ok
g(B); // ok
g(C); // ok
```

Reference - Arrays★

```
int A[4]:
int (&B) [4] = A; // ok, reference to array
int C[10][3]:
int (&D)[10][3] = C; // ok, reference to 2D array
auto c = new int[3][4]; // type is int (*)[4]
// read as "pointer to arrays of 4 int"
// int (&d)[3][4] = c; // compile error
// int (*e)[3] = c; // compile error
int (*f)[4] = c: // ok
```

```
int array[4];
// &array is a pointer to an array of size 4
int size1 = (&array)[1] - array;
int size2 = *(&array + 1) - array;
cout << size1; // print 4
cout << size2; // print 4</pre>
```

struct Member Access

- The dot (.) operator is applied to local objects and references
- The arrow operator (->) is used with a pointer to an object

```
struct A {
  int x;
};
A a; // local object
a.x; // dot syntax
A& ref = a; // reference
ref.x; // dot syntax
A* ptr = &a; // pointer
ptr->x; // arrow syntax: same of *ptr.x
```

Constants, Literals, const, constexpr,

const, constexpr, consteval,

constinit

Constants and Literals

A **constant** is an expression that can be *evaluated* at *compile-time*

A **literal** is a *fixed value* that can be assigned to a *constant*

formally, "Literals are the tokens of a C++ program that represent constant values embedded in the source code"

Literal types:

- Concrete values of the scalar types bool, char, int, float, double
- String literal of type const char[], e.g "literal"
- nullptr
- User-defined literals

const Keyword

const keyword

The const keyword indicates objects never changing value after their initialization (they must be initialized when declared)

const variables are evaluated at compile-time value if the right expression is also
evaluated at compile-time

- lacktriangledown int* o const int*
- const int* → int*

```
void f1(const int* array) {} // the values of the array cannot
                          // be modified
void f2(int* array) {}
int* ptr = new int[3];
const int* cptr = new int[3];
f1(ptr); // ok
f2(ptr); // ok
f1(cptr); // ok
// f2(cptr); // compile error
```

const Keyword and Pointers

- int* pointer to int
 - The value of the pointer can be modified
 - The elements refereed by the pointer can be modified
- const int* pointer to const int. Read as (const int)*
 - The value of the pointer can be modified
 - The elements refereed by the pointer cannot be modified
- int *const const pointer to int
 - The value of the pointer cannot be modified
 - The elements refereed by the pointer can be modified
- const int *const const pointer to const int
 - The value of the pointer cannot be modified
 - The elements refereed by the pointer cannot be modified

Note: const int* (West notation) is equal to int const* (East notation)

Tip: pointer types should be read from right to left

Common error: adding const to a pointer is <u>not</u> the same as adding const to a type alias of a pointer

```
using ptr_t = int*;
using const ptr t = const int*;
void f1(const int* ptr) {
// ptr[0] = 0; // not allowed: pointer to const objects
   ptr = nullptr; // allowed
void f3(const_ptr_t ptr) { // same as before
// ptr[0] = 0; // not allowed: pointer to const objects
   ptr = nullptr; // allowed
void f2(const ptr_t ptr) { // warning!! equal to 'int* const'
   ptr[0] = 0: // allowed!!
// ptr = nullptr; // not allowed: const pointer to modifiable objects
```

constexpr (C++11)

constexpr specifier declares that the expressions can be evaluated at compile time

- const guarantees the value of a variable to be fixed overall the execution of the program
- constexpr implies const
- constexpr helps for performance and memory usage
- constexpr could potentially impact on compilation time

constexpr Variable

constexpr variables are always evaluated at compile-time

constexpr Function

constexpr guarantees compile-time evaluation of a function as long as \underline{all} its arguments are evaluated at compile-time

- Cannot contain run-time functions, namely non-constexpr functions
- C++11: must contain exactly one return statement and it must not contain loops or switch
- C++14: no restrictions

```
constexpr int square(int value) {
    return value * value;
}
square(4); // compile-time evaluation
int a = 4; // "a" is dynamic
square(a); // run-time evaluation
```

- cannot contain run-time features such as try-catch blocks, exceptions, and RTTI
- cannot contain goto and asm statements
- cannot contain static variables
- cannot contains assert() until C++14
- must not be virtual until C++20
- undefined behavior code is not allowed, e.g. reinterpret_cast, unsafe usage of union, signed integer overflow, etc.

constexpr non-static member functions of run-time objects cannot be used even if all constrains are respected.

static constexpr *member functions* don't present this issue as they don't depend on a specific instance

```
struct A {
   constexpr int f() const { return 3; }
   static constexpr int g() { return 4; }
};
A a1:
// constexpr int x = a1.f(); // compile error
constexpr int y = a1.g(); // ok, also 'A::q()' is fine
constexpr A a2;
constexpr int x = a2.f(); // ok
```

consteval Keyword

consteval (C++20)

consteval, or *immediate functions*, guarantees compile-time evaluation of a function. A non-constant value always produces a compilation error

```
consteval int square(int value) {
    return value * value;
}

square(4);  // compile-time evaluation

int v = 4;  // "v" is dynamic

// square(v); // compile error
```

constinit Keyword

constinit (C++20)

constinit guarantees compile-time <u>initialization</u> of a variable. A non-constant value always produces a compilation error

- The value of a variable can change during the execution
- const constinit does not imply constexpr, while the opposite is true
- constexpr requires compile-time evaluation during his entire lifetime

```
constexpr int square(int value) {
    return value * value;
}
constinit int v1 = square(4);  // compile-time evaluation
v1 = 3;  // ok, v1 can change

int a = 4;  // "v" is dynamic
// constinit int v2 = square(a); // compile error
62
```

if constexpr

if constexpr C++17 feature allows to *conditionally* compile code based on a *compile-time* value

The if constexpr statement forces the compiler to evaluate the branch at compile-time (similarly to the #if preprocessor)

Note: Ternary (conditional) operator does not provide constexpr variant

if constexpr Example

```
constexpr int fib(int n) {
    return (n == 0 | | n == 1) ? 1 : fib(n - 1) + fib(n - 2);
int main() {
    if constexpr (sizeof(void*) == 8)
        return fib(5);
    else
       return fib(3);
```

Generated assembly code (x64 OS):

```
main:
  mov eax, 8
  ret
```

if constexpr Pitfalls

if constexpr works only with explicit if/else statements

```
auto f1() {
    if constexpr (my_constexpr_fun() == 1)
        return 1;

// return 2.0; compile error // this is not part of constexpr
}
```

else if branch requires constexpr

```
auto f2() {
    if constexpr (my_constexpr_fun() == 1)
        return 1;
    else if (my_constexpr_fun() == 2) // -> else if constexpr

// return 2.0; compile error // this is not part of constexpr
    else
        return 3L;
}
```

std::is_constant_evaluated()

C++20 provides std::is_constant_evaluated() utility to evaluate if the current function is evaluated at compile time

```
#include <type traits> // std::is constant evaluated
constexpr int f(int n) {
    if (std::is_constant_evaluated())
       return 0:
    return 4:
int x = f(3): // x = 0
int v = 3;
int y = f(v); // y = 4
```

std::is_constant_evaluated() has two problems that C++23 if consteval
solves:

(1) Calling a consteval function cannot be used within a constexpr function if it is called with a run-time parameter

```
consteval int g(int n) { return n * 3; }

constexpr int f(int n) {
   if (std::is_constant_evaluated()) // if consteval works fine
      return g(n);
   return 4;
}

// f(3); compiler error
```

(2) if constexpr (std::is_constant_evaluated()) is a bug as it is always evaluated to true

```
constexpr int f(int x) {
   if constexpr (std::is_constant_evaluated()) // if consteval avoids this error
     return 3;
   return 4;
}
```

volatile **Keyword** ★

volatile Keyword

volatile

volatile is a hint to the compiler to avoid aggressive memory optimizations involving a pointer or an object

Use cases:

- Low-level programming: driver development, interaction with assembly, etc.
 (force writing to a specific memory location)
- Multi-thread program: variables shared between threads/processes to communicate (don't optimize, delay variable update)
- Benchmarking: some operations need to not be optimized away

Note: volatile reads/writes can still be reordered with respect to non-volatile ones

volatile **Keyword** - **Example**

The following code compiled with -03 (full optimization) and without volatile works fine

Conversion

Explicit Type

Old style cast: (type) value

New style cast:

- static_cast performs compile-time (not run-time) type check. This is the safest
 cast as it prevents accidental/unsafe conversions between types
- const_cast can add or cast away (remove) constness or volatility
- reinterpret_cast

```
reinterpret_cast<T*>(v) equal to (T*) v
reinterpret_cast<T&>(v) equal to *((T*) &v)
```

const_cast and reinterpret_cast do not compile to any CPU instruction

Static cast vs. old style cast:

Const cast:

```
const int     a = 5;
const_cast<int>(a) = 3; // ok, but undefined behavior
```

Reinterpret cast: (bit-level conversion)

Print the value of a pointer

Array reshaping

```
int a[3][4];
int (&b)[2][6] = reinterpret_cast<int (&)[2][6]>(a);
int (*c)[6] = reinterpret_cast<int (*)[6]>(a);
73/81
```

Pointer Aliasing

One pointer aliases another when they both point to the same memory location

Type Punning

Type punning refers to circumvent the type system of a programming language to achieve an effect that would be difficult or impossible to achieve within the bounds of the formal language

The compiler assumes that the **strict aliasing rule** is never violated: Accessing a value using a type which is different from the original one is not allowed and it is classified as undefined behavior

```
// slow without optimizations. The branch breaks the CPU instruction pipeline
float abs(float x) {
    return (x < 0.0f) ? -x : x;
// optimized by hand
float abs(float x) {
    unsigned uvalue = reinterpret_cast<unsigned&>(x);
    unsigned tmp = uvalue & 0x7FFFFFFF; // clear the last bit
    return reinterpret_cast<float&>(tmp);
// this is undefined behavior!!
```

GCC warning (not clang): -Wstrict-aliasing

■ What is the Strict Aliasing Rule and Why do we care?

blog.qt.io/blog/2011/06/10/type-punning-and-strict-aliasing

memcpy and std::bit_cast

The right way to avoid undefined behavior is using memcpy

```
float v1 = 32.3f;
unsigned v2;
std::memcpy(&v2, &v1, sizeof(float));
// v1, v2 must be trivially copyable
```

C++20 provides std::bit_cast safe conversion for replacing reinterpret_cast

```
float    v1 = 32.3f;
unsigned v2 = std::bit_cast<unsigned>(v1);
```

sizeof Operator

sizeof operator

sizeof

The sizeof is a compile-time operator that determines the size, in bytes, of a variable or data type

- sizeof returns a value of type size_t
- sizeof(anything) never returns 0 (*except for arrays of size 0)
- sizeof(char) always returns 1
- When applied to structures, it also takes into account the internal padding
- When applied to a reference, the result is the size of the referenced type
- sizeof(incomplete type) produces compile error, e.g. void
- sizeof(bitfield member) produces compile error

gcc allows array of size 0 (not allowed by the C++ standard)

```
sizeof(int); // 4 bytes
sizeof(int*) // 8 bytes on a 64-bit OS
sizeof(void*) // 8 bytes on a 64-bit OS
sizeof(size_t) // 8 bytes on a 64-bit OS
```

```
struct A {
    int x; // 4-byte alignment
    char y; // offset 4
};
sizeof(A); // 8 bytes: 4 + 1 (+ 3 padding), must be aligned to its largest member
struct B {
    int x; // offset 0 -> 4-byte alignment
    char y; // offset 4 -> 1-byte alignment
    short z: // offset 6 -> 2-byte alignment
};
sizeof(B); // 8 bytes : 4 + 1 (+ 1 padding) + 2
struct C {
    short z; // offset 0 -> 2-byte alignment
    int x; // offset 4 -> 4-byte alignment
    char y; // offset 8 -> 1-byte alignment
};
sizeof(C); // 12 bytes : 2 (+ 2 padding) + 4 + 1 + (+ 3 padding)
```

```
char a;
char \& b = a:
sizeof(&a); // 8 bytes in a 64-bit OS (pointer)
sizeof(b); // 1 byte, equal to sizeof(char)
               // NOTE: a reference is not a pointer
// SPECIAL CASES
struct A {};
sizeof(A); // 1 : sizeof never return 0
A array1[10];
sizeof(array1); // 1 : array of empty structures
int array2[0]; // only qcc
sizeof(array2); // 0 : special case
```

sizeof and Size of a Byte

Interesting: C++ does not explicitly define the size of a byte (see Exotic architectures the standards committees care about)
