C++ Templates: The Complete Guide (2nd)
D. Vandevoorde, N. M. Josuttis, D. Gregor, 2017

Function Template

Template

A **template** is a mechanism for generic programming to provide a *"schema"* (or *placeholders*) to represent the structure of an entity

In C++, *templates* are a compile-time functionality to represent:

- A family of **functions**
- A family of **classes**
- A family of **variables** C++14

The problem: We want to define a function to handle different types

```
int add(int a, int b) {
    return a + b;
}

float add(float a, float b) { // overloading
    return a + b;
}

char   add(char a, char b)    { ... } // overloading
ClassX add(ClassX a, ClassX b) { ... } // overloading
```

- Redundant code!!
- How many functions we have to write!?
- If the user introduces a new type we have to write another function!!

Function Template

A **function template** is a function schema that operates with *generic* types (independent of any particular type) or concrete values

A function template works with multiple types without repeating the entire code for each of them

```cpp
template<typename T> // or template<class T>
T add(T a, T b) {
    return a + b;
}

int   c1 = add(3, 4);        // c1 = 7
float c2 = add(3.0f, 4.0f); // c2 = 7.0f
```

Templates: Benefits and Drawbacks

Benefits

- **Generic Programming**: Less code and reusable. Reduce *redundancy*, better *maintainability* and *flexibility*

- **Performance**. Computation can be done/optimized at compile-time $\rightarrow$ *faster*

Drawbacks

- **Readability**. "With respect to C++, the syntax and idioms of templates are *esoteric* compared to conventional C++ programming, and templates can be very difficult to understand" [wikipedia] $\rightarrow$ hard to read, cryptic error messages

- **Compile Time/Binary Size**. Templates are implicitly instantiated for every distinct parameters

Template Instantiation

The **template instantiation** is the substitution of template parameters with concrete values or types

The compiler *automatically* generates a **function implementation** for <u>each</u> template instantiation

```cpp
template<typename T>
T add(T a, T b) {
    return a + b;
}
add(3, 4);       // generates: int   add(int, int)
add(3.0f, 4.0f); // generates: float add(float, float)
add(2, 6);       // already generated
// other instances are not generated
// e.g. char add(char,char)
```

Implicit and Explicit Template Instantiation

Implicit Template Instantiation

Implicit template instantiation occurs when the compiler generates code depending on the *deduced argument types* or the *explicit template arguments* and only when the definition is needed

Explicit Template Instantiation

Explicit template instantiation occurs when the compiler generates code depending only on the *explicit template arguments* specified in the declaration. Useful when dealing with multiple translation units to reduce the binary size

Implicit and Explicit Template Instantiation

```cpp
template<typename T>
void f(T a) {}

void g() {
    f(3);                  // generates: void f(int) → implicit
    f<short>(3.0);         // generates: void f(short) → implicit
}

template void f<int>(int); // generates: void f(int) → explicit
```

Template Parameters

Template Parameters are the names following the `template` keyword

```cpp
template<typename T>
void f() {}

f<int>();
```

`typename T` is the **template parameter**

`int` is the **template argument**

A **template parameter** can be a *generic type*, i.e. `typename`, as well as a *non-type template parameters* (NTTP), e.g. `int`, `enum`, etc.

The **template argument** of a *generic type* is a builtin or user-declared type, while a *concrete value* for a *non-type template parameter*

int **parameter**

```cpp
template<int A, int B>
int add_int() {
    return A + B; // sum is computed at compile-time
}                // e.g. add_int<3, 4>();
```

enum **parameter**

```cpp
enum class Enum { Left, Right };

template<Enum Z>
int add_enum(int a, int b) {
    return (Z == Enum::Left) ? a + b : a;
}       // e.g. add_enum<Enum::Left>(3, 4);
```

- **Ceiling division**

```cpp
template<int DIV, typename T>
T ceil_div(T value) {
    return (value + DIV - 1) / DIV;
}
// e.g. ceil_div<5>(11); // returns 3
```

- **Rounded division**

```cpp
template<int DIV, typename T>
T round_div(T value) {
    return (value + DIV / 2) / DIV;
}
// e.g. round_div<5>(11); // returns 2 (2.2)
```

Since DIV is known at compile-time, the compiler can heavily <u>optimize</u> the division
(almost for every numbers, not just for power of two)   14/48

C++11 **Template parameters can have default values**

(only at the end of the parameter list)

```cpp
// template<int A = 3, int B>   // compile error
template<int A = 3>
int print1() {
    cout << A;
}

print1<2>(); // print 2
print1<>();  // print 3 (default)
print1();    // print 3 (default)
```

Template parameters may have no name

```cpp
void f() {}

template<typename = void>
void g() {}

int main() {
    g();  // generated
}
```

f() is always generated in the final code

g() is generated in the final code only if it is called

C++11 **Unlike function parameters, template parameters can be initialized by previous values**

```cpp
template<int A, int B = A + 3>
void f() {
    cout << B;
}

template<typename T, int S = sizeof(T)>
void g(T) {
    cout << S;
}

f<3>();  // B is 6
g(3);    // S is 4
```

Function Template Overloading

Template Functions can be *overloaded*

```cpp
template<typename T>
T add(T a, T b) {
    return a + b;
} // e.g add(3, 4);

template<typename T>
T add(T a, T b, T c) { // different number of parameters
    return a + b + c;
} // e.g add(3, 4, 5);
```

Also templates themselves can be *overloaded*

```cpp
template<int C, typename T>
T add(T a, T b) {       // it is not in conflict with
    return a + b + C; // T add(T a, T b)
}                      // "C" is part of the signature
```

Template Specialization

Template specialization refers to the concrete implementation for a specific combination of template parameters

The problem:

```
template<typename T>
bool compare(T a, T b) {
    return a < b;
}
```

The direct comparison between two floating-point values is dangerous due to rounding errors

Solution: Template specialization

```
template<>
bool compare<float>(float a, float b) {
    return ...    // a better floating point implementation
}
```

Full Specialization: *Function* templates can be specialized only if **ALL** template arguments are specialized

Template Variable

Template Variable

C++14 allows variables with templates

A template variable can be considered a special case of a template class

```cpp
template<typename T>
constexpr T pi{ 3.1415926535897932385 }; // variable template

template<typename T>
T circular_area(T r) {
    return pi<T> * r * r; // pi<T> is a variable template instantiation
}

circular_area(3.3f); // float
circular_area(3.3); // double
// circular_area(3); // compile error, narrowing conversion with "pi"
```

Template Parameter Types

Template Parameter Types

Template parameters can be:

- *integral type*
- `enum`, `enum class`
- *floating-point type* C++20
- `auto` placeholder C++17
- *class literals* and *concepts* C++20
- *generic type* `typename`

and rarely:

- *function*
- *reference/pointer* to global `static` function or object
- *pointer to member type*
- `nullptr_t` C++14

Generic Type Notes

Pass multiple values and floating-point types

```cpp
// template<float V>  // compiler error
// void print() {      // not valid before C++20

template<typename T>
void print() {
    cout << T::x << ", " << T::y;
}

struct Multi {
    static const    int   x = 1;
    static constexpr float y = 2.0f; // preferred
};

print<Multi>(); // print 2.0, 3.0
```

`auto` Placeholder

C++17 introduces automatic deduction of *non-type* template parameters with the `auto` keyword

```cpp
template<int X, int Y>
void f() {}

template<typename T1, T1 X, typename T2, T2 Y>
void g1() {} // before C++17

template<auto X, auto Y>
void g2() {}

f<2u, 2u>();          // X: int, Y: int
g1<int, 2, char, 'a'>(); // X: int, Y: char
g2<2, 'a'>();         // X: int, Y: char
```

Class Template Parameter Type

C++20 A *non-type template parameter* of a **class literal type**:

- A *class literal* is a class that can be assigned to `constexpr` variable
- All *base* classes and *non-static data members* are `public` and `non-mutable`
- All *base* classes and *non-static data members* have the same properties

```cpp
#include <array>
struct A {
    int x;
    constexpr A(int x1) : x{x1} {}
};
template<A a>
void f() { std::cout << a.x; }

template<std::array array>
void g() { std::cout << array[2]; }

f<A{5}>();          // print '5'
g<std::array{1,2,3}>(); // print '3'
```

Array and pointer

```cpp
template<int* ptr>    // pointer
void g() {
    cout << ptr[0];
}

template<int (&array)[3]> // reference
void f() {
    cout << array[0];
}

int array[] = {2, 3, 4}; // global

int main() {
    f<array>(); // print 2
    g<array>(); // print 2
}
```

Class member

```cpp
struct A {
    int x   = 5;
    int y[3] = {4, 2, 3};
};

template<int A::*x>      // pointer to
void h1() {}            // member type

template<int (A::*y)[3]> // pointer to
void h2() {}            // member type

int main() {
    h1<&A::x>();
    h2<&A::y>();
}
```

Function

```
template<int (*)(int, int)> // <-- signature of "f"
int apply1(int a, int b) {
    return g(a, b);
}

int f(int a, int b) {
    return a + b;
}

template<decltype(f)>        // alternative syntax
void apply2(int a, int b) {
    return g(a, b);
}

int main() {
    apply1<f>(2, 3); // return 5
    apply2<f>(2, 3); // return 5
}
```

Compile-Time Utilities

C++11 `static_assert` **is used to test a software assertion at** <u>**compile-time**</u>

If the *static assertion* fails, the program does not compile

```cpp
static_assert(2 + 2 == 4, "test1"); // ok, it compiles
static_assert(2 + 2 == 5, "test2"); // compile error
static_assert(sizeof(void*) * 8 == 64, "test3");
// depends on the OS (32/64-bit)
```

```cpp
template<typename T, typename R>
void f() {
    static_assert(sizeof(T) == sizeof(R)); // message not needed in C++17
}

f<int, unsigned>(); // ok, it compiles
// f<int, char>();  // compile error
```

using **keyword (C++11)**

The using keyword introduces an *alias-declaration* or *alias-template*

- using is an enhanced version of typedef with a more readable syntax
- using can be combined with templates, as opposite to typedef
- using is useful to simplify complex template expression
- using allows to introduce new names for partial and full specializations

```cpp
typedef int distance_t; // equal to:

using distance_t = int;
```

```cpp
typedef void (*function)(int, float); // equal to:

using function = void (*)(int, float);
```

Full/Partial specialization alias:

```cpp
template<typename T, int Size>
struct Vector {};                  // see next lecture for further details
                                   // on class template

template<int Size>
using Bitset = Vector<bool, Size>; // partial specialization alias

using IntV4 = Vector<int, 4>;      // full specialization alias
```

Accessing a type within a structure:

```cpp
struct A {
    using type = int;
};
using Alias = A::type;
```

C++11 `decltype` **keyword captures the type of an *entity* or an *expression***

- `decltype` never executes, it is always evaluated at compile-type

```cpp
int      x = 3;
int&     y = x;
const int z = 4;
int      array[2];
void     f(int, float);

decltype(x);        // int
decltype(2 + 3.0);  // double
decltype(y);        // int&
decltype(z);        // const int
decltype(array);    // int[2]
decltype(f(1, 2.0f)); // void

using function = decltype(f);
```

```
bool f(int) { return true; }

struct A {
    int x;
};
int x = 3;
const A a;

decltype(x);     // int
decltype((x));   // int&

decltype(f);     // bool (int)
decltype((f));   // bool (&)(int)

decltype(a.x);   // int
decltype((a.x)); // const int
```

C++11

```
template<typename T, typename R>
decltype(T{} + R{}) add(T x, R y) {
    return x + y;
}

unsigned v1 = add(1, 2u);
double   v2 = add(1.5, 2u);
```

C++14

```
template<typename T, typename R>
auto add(T x, R y) {
    return x + y;
}
```

Type Traits

Introspection

Introspection is the ability to inspect a type and query its properties

Reflection

Reflection is the ability of a computer program to examine, introspect, and modify its own structure and behavior

C++ provides compile-time reflection and introspection capabilities through type traits

Type traits (C++11)

Type traits define a compile-time interface to *query* or *modify* the properties of types

The problem:
```cpp
template<typename T>
T integral_div(T a, T b) {
    return a / b;
}

integral_div(7, 2);    // returns 3 (int)
integral_div(7l, 2l);  // returns 3 (long int)
integral_div(7.0, 3.0); // !!! a floating-point value is not an integral type
```

Two alternatives: (1) Specialize (2) Type Traits + static_assert

If we want to **prevent floating-point/other objects division at compile-time**, a first solution consists in specialize for all integral types

```cpp
template<typename T>
T integral_div(T a, T b); // declaration (error for other types)

template<>
char integral_div<char>(char a, char b) {   // specialization
    return a / b;
}
template<>
int  integral_div<int>(int a, int b) {       // specialization
    return a / b;
}
...unsigned char
...short
...
```

The best solution is to use **type traits**

```cpp
#include <type_traits>        // <-- std type traits library
template<typename T>
T integral_div(T a, T b) {
    static_assert(std::is_integral<T>::value,
                  "integral_div accepts only integral types");
    return a / b;
}
```

`std::is_integral<T>` is a `struct` with a `static constexpr` boolean field `value`

`value` is <u>true</u> if T is a `bool`, `char`, `short`, `int`, `long`, `long long`, <u>false</u> otherwise

---

C++17 provides utilities to improve the readability of type traits

```cpp
std::is_integral_v<T>;  // std::is_integral<T>::value
```

37/48

- `is_integral` checks for an integral type (`bool` , `char` , `unsigned char` , `short` , `int` , `long` , etc.)

- `is_floating_point` checks for a floating-point type (`float` , `double`)

- `is_arithmetic` checks for a integral or floating-point type

- `is_signed` checks for a signed type (`float` , `int` , etc.)

- `is_unsigned` checks for an unsigned type (`unsigned` , `bool` , etc.)

- `is_enum` checks for an enumerator type (`enum` , `enum class`)

- `is_void` checks for (`void`)

- `is_pointer` checks for a pointer (`T*`)

- `is_nullptr` checks for a (`nullptr`) C++14

Entity type queries:

- `is_reference` checks for a reference (`T&`)

- `is_array` checks for an array (`T (&)[N]`)

- `is_function` checks for a function type

Class queries:

- `is_class` checks for a class type (`struct` , `class`)

- `is_abstract` checks for a class with at least one pure virtual function

- `is_polymorphic` checks for a class with at least one virtual function

Type property queries:

- `is_const` checks if a type is `const`

Type relation:

- `is_same<T, R>` checks if `T` and `R` are the same type

- `is_base_of<T, R>` checks if `T` is base of `R`

- `is_convertible<T, R>` checks if `T` can be converted to `R`

Full list: en.cppreference.com/w/cpp/header/type_traits

Example - `const` Deduction

```cpp
#include <type_traits>
template<typename T>
void f(T x) {  cout << std::is_const_v<T>;  }

template<typename T>
void g(T& x) {  cout << std::is_const_v<T>;  }

template<typename T>
void h(T& x) {
   cout << std::is_const_v<T>;
   x = nullptr; // ok, it compiles for T: (const int)*
}
const int a = 3;
f(a); // print false, "const" drop in pass by-value
g(a); // print true
const int* b = new int;
h(b); // print false!! T: (const int)*
```

Example - Type Relation

```cpp
#include <type_traits>
template<typename T, typename R>
T add(T a, R b) {
    static_assert(std::is_same_v<T, R>, "T and R must have the same type")
    return a + b;
}
add(1, 2);        // ok
// add(1, 2.0); // compile error, "T and R must have the same type"
```

```cpp
#include <type_traits>
struct A {}
struct B : A {}

std::is_base_v<A, B>;            // true
std::is_convertible_v<int, float>; // true
```

Type Manipulation

Type traits allow also to manipulate types by using the `type` field

Example: produce `unsigned` from `int`

```cpp
#include <type_traits>

using U = typename std::make_unsigned<int>::type; // see next lecture to understand
                                                  // why 'typename' is needed here
U y = 5;  // unsigned
```

C++14 provides utilities to improve the readability of type traits

```cpp
std::make_unsigned_t<T>;  // instead of 'typename std::make_unsigned<T>::type'
```

Signed and Unsigned types:

- `make_signed` makes a signed type

- `make_unsigned` makes an unsigned type

Pointers and References:

- `remove_pointer` remove pointer (`T*` $\rightarrow$ `T`)

- `remove_lvalue_reference` remove reference (`T&` $\rightarrow$ `T`)

- `add_pointer` add pointer (`T` $\rightarrow$ `T*`)

- `add_lvalue_reference` add reference (`T` $\rightarrow$ `T&`)

`const` **specifiers:**

- `remove_const` remove `const` (`const T` $\rightarrow$ `T`)

- `add_const` add `const`

Other type transformation:

- `common_type`<T, R> returns the common type between `T` and `R`

- `conditional`<pred, T, R> returns `T` if `pred` is `true`, `R` otherwise

- `decay`<T> returns the same type as a function parameter passed by-value

Type Manipulation Example

```cpp
#include <type_traits>
template<typename T>
void f(T ptr) {
    using R = std::remove_pointer_t<T>;
    R x = ptr[0]; // char
}

template<typename T>
void g(T x) {
    using R = std::add_const_t<T>;
    R y = 3;
//  y  = 4;    // compile error
}

char a[] = "abc";
f(a); // T: char*
g(3); // T: int
```

`std::common_type` Example

```cpp
#include <type_traits>

template<typename T, typename R>
std::common_type_t<R, T> // <-- return type
add(T a, R b) {
    return a + b;
}

// we can also use decltype to derive the result type
using result_t = decltype(add(3, 4.0f));
result_t x = add(3, 4.0f);
```

`std::conditional` Example

```cpp
#include <type_traits>

template<typename T, typename R>
auto f(T a, R b) {
    constexpr bool pred = sizeof(T) > sizeof(R);
    using S = std::conditional_t<pred, T, R>;
    return static_cast<S>(a) + static_cast<S>(b);
}

f(   2,  'a'); // return 'int'
f(   2, 2ull); // return 'unsigned long long'
f(2.0f, 2ull); // return 'unsigned long long'
```
