Table of Context

Table of Context

Function Template

Template Overview

Template

A **template** is a mechanism for generic programming to provide a *"schema"* (or *placeholders*) to represent the structure of an entity

In C++, *templates* are a compile-time functionality to represent:

- A family of **functions**
- A family of **classes**
- A family of **variables** C++14

Templates are a way to make code *more reusable* and *faster*

negative sides: hard to read, cryptic error messages, larger binary size, and higher compile time

The problem: We want to define a function to handle different
types

```cpp
int add(int a, int b) {
    return a + b;
}

float add(float a, float b) { // overloading
    return a + b;
}

char   add(char a, char b)     { ... } // overloading
ClassX add(ClassX a, ClassX b) { ... } // overloading
```

- Redundant code!!
- How many functions we have to write!?
- If the user introduces a new type we have to write another
  function!!

Function Templates

Function templates are special functions that can operate with *generic* types (independent of any particular type)

Allow to create a function template whose functionality can be adapted to more than one type or class without repeating the entire code for each type

```
template<typename T>
T add(T a, T b) {
    return a + b;
}

int   c1 = add(3, 4);          // c1 = 7
float c2 = add(3.0f, 4.0f);    // c2 = 7.0f
int   c3 = add<int>(3.0f, 4.0f); // c3 = 7 (int forced)
```

Templates: Benefits and Drawbacks

Benefits

- **Generic Programming**: Less code and reusable. Reduce *redundancy*, better *maintainability* and *flexibility*
- **Performance**. Computation can be done at compile-time

Drawbacks

- **Readability**. With respect to C++, the syntax and idioms of templates are *esoteric* compared to conventional C++ programming, and templates can be very difficult to understand [wikipedia]
- **Compile Time**. Templates are implicitly instantiated for every different parameters

```
template<typename T>
```

`typename T` is a **template parameter**

In common cases, a **template parameter** can be:

- *generic type*: `typename`

- *non-type template parameters*
    - *integral type*: `int`, `char`, etc. (but not floating point)
    - *enumerator*: `enum`, *enumerator class*: `enum class`

int parameter

```cpp
template<int A, int B>
int add_int() {
    return A + B; // sum is computed at compile-time
}                 // e.g. add_int<3, 4>();
```

enum parameter

```cpp
enum class Enum { Left, Right };

template<Enum Z>
int add_enum(int a, int b) {
    return (Z == Enum::Left) ? a + b : a;
}        // e.g. add_enum<Enum::Left>(3, 4);
```

- **Ceiling division**

```cpp
template<int DIV, typename T>
T ceil_div(T value) {
    return (value + DIV - 1) / DIV;
}
// e.g. ceil_div<5>(11); // returns 3
```

- **Rounded division**

```cpp
template<int DIV, typename T>
T round_div(T value) {
    return (value + DIV / 2) / DIV;
}
// e.g. round_div<5>(11); // returns 2 (2.2)
```

Since DIV is known at compile-time, the compiler can heavily optimize the division (almost for every numbers, not just for power of two)

Code Generation

The compiler generates a specific **function implementation** for
every template parameter instance

```cpp
template<typename T>
T add(T a, T b) {
    return a + b;
}

add(3, 4);       // generates: int   add(int, int)
add(3.0f, 4.0f); // generates: float add(float, float)
add(2, 6);       // already generated
// other instances are not generated
// e.g. char add(char,char)
```

C++11 **Template parameters can have default values**
(only at the end of the parameter list)

```cpp
// template<int A = 3, int B>   // compile error
template<int A = 3>
int print1() {
    cout << A;
}

print1<2>(); // print 2
print1<>();  // print 3 (default)
print1();    // print 3 (default)
```

Template parameters may have no name

```cpp
void f() {}

template<typename = void>
void g() {}

int main() {
    g();  // generated
}
```

f() is <u>always</u> generated in the final code

g() is generated in the final code <u>only</u> if it is called

**Unlike function parameters, template parameters can be
initialized by previous values**

```cpp
template<int A, int B = A + 3>
void f() {
    cout << B;
}

template<typename T, int S = sizeof(T)>
void g(T) {
    cout << S;
}

f<3>(); // B is 6
g(3);   // S is 4
```

Specialization

Specialization refers to the concrete implementation for a specific combination of template parameters

The problem:

```
template<typename T>
T compare(T a, T b) {
    return a < b;
}
```

The direct comparison between two floating-point values is dangerous due to rounding errors

Solution: Template specialization

```
template<>
float compare<float>(float a, float b) {
    return ...    // floating point relative error implementation
}                 // see "Basic I" lecture
```

Full Specialization: *Function* templates can be specialized only if
ALL template arguments are specialized

Function Template - Overloading

Template Functions can be *overloaded*

```
template<typename T>
T add(T a, T b) {
    return a + b;
} // e.g add(3, 4);

template<typename T>
T add(T a, T b, T c) { // different number of parameters
    return a + b + c;
} // e.g add(3, 4, 5);
```

Also templates themselves can be *overloaded*

```
template<int C, typename T>
T add(T a, T b) {       // it is not in conflict with
    return a + b + C;   // T add(T a, T b)
}                       // "C" is part of the signature
```

`auto` Deduction

C++17 introduces automatic deduction of *non-type* template parameters with the `auto` keyword

```cpp
template<int X, int Y>
void f() {}

template<auto X, auto Y>
void g() {}

f<2u, 2u>();    // X: int, Y: int

g<2, 3>();      // X: int,      Y: int
g<2u, 2u>();    // X: unsigned, Y: unsigned
g<2, 3u>();     // X: int,      Y: unsigned
```

Compile-Time Utilities

static_assert (**C++11**) is used to test a software assertion at compile-time

If the static assertion fails, the program does not compile

```cpp
static_assert(2 + 2 == 4, "test1"); // ok, it compiles
static_assert(2 + 2 == 5, "test2"); // compile error
static_assert(sizeof(void*) * 8 == 64, "test3");
// depends on the OS (32/64-bit)
```

```cpp
template<typename T, typename R>
void f(T, R) {
    static_assert(sizeof(T) == sizeof(R), "test4");
}

f<int, unsigned>(); // ok, it compiles
// f<int, char>(); // compile error
```

decltype Keyword (value)

decltype is a keyword used to get the type of an *entity* or an *expression*

- decltype never executes, it only evaluates at compile-type

```cpp
int       x = 3;
int&      y = x;
const int z = 4;
int array[2];

decltype(x);       // int
decltype(2 + 3.0); // double
decltype(y);       // int&
decltype(z);       // const int
decltype(array);   // int[2]
```

decltype Keyword ((expression))

```cpp
bool f(int) { return true; }

struct A {
    int x;
};
int x = 3;
const A a;

decltype(x);    // int
decltype((x));  // int&

decltype(f);    // bool
decltype((f));  // bool (*)(int)

decltype(a.x);   // int
decltype((a.x)); // const int
```

`decltype` Keyword + Function templates

C++11

```
template<typename T, typename R>
decltype(T{} + R{}) add(T x, R y) {
    return x + y;
}

unsigned v1 = add(1, 2u);
double   v2 = add(1.5, 2u);
```

C++14

```
template<typename T, typename R>
auto add(T x, R y) {
    return x + y;
}
```

using **Keyword**

using **keyword**

using introduces *alias templates* (synonyms)

- using is an enhanced version of typedef
- using keyword is useful to simplify complex template expression
- using keyword allows defining partial and full specialization

```cpp
template<typename T, typename R>
struct A {};

template<typename T>
using Alias = A<T, int>;        // called "Alias Template"

using IntAlias = A<int, int>;

Alias<char> a; // A<char, int>
IntAlias    b; // A<int,  int>
```

Type Traits

Introspection

Introspection is the ability to inspect a type and retrieve its various qualities

Reflection

Reflection is the ability of a computer program to examine, introspect, and modify its own structure and behavior at runtime

C++ provides compile-time reflection and introspection capabilities through type traits

Type traits

Type traits (C++11) defines a <u>compile-time</u> interface to query or modify the properties of types

The problem:
```
template<typename T>
T floor_div(T a, T b) {
    return a / b;
}

floor_div(7, 2);     // returns 3 (int)
floor_div(7l, 2l);   // returns 3 (long int)
floor_div(7.0, 3.0); // ??? it compiles, but the result is
                     // not what we expect
```

Two alternatives: (1) Specialize (2) Type Traits + static_assert

If we want to **prevent floating-point division at compile-time** a
first solution consists in specialize for all "integral" types

```
template<typename T>
T floor_div(T a, T b); // declaration (error for other types)

template<>
char floor_div<char>(char a, char b) {   // specialization
    return a / b;
}
template<>
int  floor_div<int>(int a, int b) {      // specialization
    return a / b;
}
...unsigned char
...short
...
```

Very redundant!!   25/43

The best solution is to use **type traits**

```cpp
#include <type_traits>        // <-- std type traits library

template<typename T>
T floor_div(T a, T b) {
    static_assert(std::is_integral<T>::value,
                  "floor_div accepts only integral types");
    return a / b;
}
```

std::is_integral<T> is a struct with a boolean field `value`

It is <u>true</u> if T is a `bool`, `char`, `short`, `int`, `long`,
`long long`, <u>false</u> otherwise

Full list: en.cppreference.com/w/cpp/header/type_traits

- `is_integral` checks for an integral type (`bool`, `char`, `unsigned char`, `short`, `unsigned short`, `int`, `long`, etc.)

- `is_floating_point` checks for a floating-point type (`float`, `double`)

- `is_arithmetic` checks for a integral or floating-point type

- `is_signed` checks for a signed type (`float`, `int`, etc.)

- `is_unsigned` checks for an unsigned type (`unsigned T`, `bool`, etc.)

- `is_enum` checks for an enumerator type (`enum`, `enum class`)

- `is_void` checks for (void)

- `is_pointer` checks for a pointer (T*)

- `is_nullptr` checks for a (nullptr) C++14

- `is_reference` checks for a reference (T&)

- `is_array` checks for an array (T (&)[N])

- `is_function` checks for a function type

- `is_const` checks if a type is const

- `is_class` checks for a class type (struct, class, not enum class)

- `is_empty` checks for empty class types (struct A {})

- `is_abstract` checks for a class with at least one pure virtual function

- `is_polymorphic` checks for a class with at least one virtual function

- `is_final` checks for a class that cannot be extended

Example (const Deduction)

```cpp
#include <type_traits>

template<typename T>
void f(T x) {  cout << std::is_const<T>::value;  }

template<typename T>
void g(T& x) {  cout << std::is_const<T>::value;  }

template<typename T>
void h(T& x) {
   cout << std::is_const<T>::value;
   x = nullptr; // ok, it compiles for T: (const int)*
}

const int a = 3;
f(a); // print false, "const" drop in pass by-value
g(a); // print true
const int* b = nullptr;
h(b); // print false!! T: (const int)*
```

Type traits allows also to manipulate types by using the `type`
field (can be used also in the return type of a function)

Example: convert `int` to `unsigned`

```cpp
#include <type_traits>

using T = int;
T x = -3; // int

using R = typename std::make_unsigned<int>::type;
R y = 5;  // unsigned
```

In general, type traits (or other *templated* structures) depends on a template (*dependent name*) (int in the previous example). In these cases, the compiler needs to known if `::type` is a <u>type</u> or a <u>static member</u> in advance

The keyword `typename` placed before the *structure template* solves this ambiguous

e.g. `typename std::make_unsigned<T>::type` is a type

The expression can be combined with `using` or typedef to improve the readability

e.g. `using R = typename std::make_unsigned<int>::type;`

Signed and Unsigned types:

- `make_signed` makes a type signed

- `make_unsigned` makes a type unsigned

Pointers and References:

- `remove_pointer` remove pointer (T* → T)

- `remove_lvalue_reference` remove reference (T& → T)

- `add_pointer` add pointer (T → T*)

- `add_lvalue_reference` add reference (T → T&)

Const-Volatile Specifiers:

- `remove_const` remove const (const T → T)

- `remove_volatile` remove volatile (volatile T → T)

- `remove_cv` remove const and volatile

- `add_const` add const

```cpp
#include <type_traits>

template<typename T>
void f(T ptr) {
    using R = typename std::remove_pointer<T>::type;
    R x = ptr[0]; // char
}

template<typename T>
void g(T x) {
    using R = typename std::add_const<T>::type;
    R y = 3;
//  y   = 4;    // compile error
}

char a[] = "abc";
int  b   = 3;
f(a); // T: char*
g(b); // T: int
```

Type Relation and Transformation

Type relation:

- `is_same<T, R>` check if T and R are the same type

- `is_base_of<T, R>` check if T is base of R

- `is_convertible<T, R>` check if T can be converted to R

Type Transformation:

- `common_type<T, R>` returns the common type between T and R

- `conditional<pred, T, R>` returns T if pred is true, R otherwise

- `decay<T>` returns the same type as function pass-by-value

Example

```cpp
#include <type_traits>

template<typename T, typename R>
T add(T a, R b) {
    static_assert(std::is_same<T, R>::value,
                  "T and R must be the same)
    return a + b;
}

struct A {}
struct B : A {}

add(1, 2);        // ok
// add(1, 2.0);   // compile error
std::is_base<A, B>::value; // true
std::is_base<A, A>::value; // true
std::is_convertible<int, float>::value; // true
```

std::common_type example

```cpp
#include <type_traits>

template<typename T, typename R>
typename std::common_type<R, T>::type // <-- return type
add(T a, R b) {
    return a + b;
}

add(3, 4.0f); // .. but we don't know the type of the result

// we can use decltype to derive the result type of
// a generic expression
using result_t = decltype(add(3, 4.0f));
result_t x = add(3, 4.0f);
```

std::conditional **example**

```cpp
#include <type_traits>

template<typename T, typename R>
void f(T a, R b) {
    const bool pred = sizeof(T) > sizeof(R);
    using S = typename std::conditional<pred, T, R>::type;
    S result = a + b;
}

f(2, 'a'); // S: int
f(2, 2ull); // S: unsigned long long
```

Type Traits in C++14/17

C++14 and C++17 provide utilities to improve the readability of
type traits

```cpp
#include <type_traits>

std::is_signed_v<int>;        // std::is_signed<int>::value
std::is_same_v<int, float>;  // std::same<int, float>::value

std::make_unsigned_t<int>;
// instead of: typename std::make_unsigned<int>::type

std::conditional_t<true, int, float>;
// instead of: typename std::conditional<true, int, float>::type
}
```

Template Parameters

Template Parameters

Template parameters can be:

- *integral type* (`int`, `char`, etc) (not floating point)
- *enumerator, enumerator class*
- *generic type* (**can be anything**)

But also:

- *function*
- *reference* to global static function or object
- `pointer` to global static function or object
- *pointer to member type* cannot be used directly, but the function can be specialized
- `nullptr_t`

C++20 allows floating-point types and classes

Generic Type Example

Pass multiple values and floating-point types

```cpp
// template<float V>  // compiler error
// void print() {     // not valid

template<typename T>  // generic typename
void print() {
    cout << T::x << ", " << T::y;
// cout << T::z;  // compiler error
}                 // "z" is not a member of Multi

struct Multi {
    static const    int   x = 1;
    static constexpr float y = 2.0f;
};

print<Multi>();  // print 2.0, 3.0
```

Array and pointer

```cpp
#include <iostream>

template<int* ptr>    // pointer
void g() {
    std::cout << ptr[0];
}

template<int (&array)[3]> // reference
void f() {
    std::cout << array[0];
}

int array[] = {2, 3, 4}; // global

int main() {
    f<array>(); // print 2
    g<array>(); // print 2
}
```

Class member

```cpp
struct A {
    int x    = 5;
    int y[3] = {4, 2, 3};
};

template<int A::*z>       // pointer to
void h1() {}             // member type

template<int (A::*z)[3]> // pointer to
void h2() {}             // member type

int main() {
    h1<&A::x>(); // print 5
    h2<&A::y>(); // print 4
}
```

Function

```cpp
template<int (*)(int, int)> // <-- signature of "f"
int apply1(int a, int b) {
    return g(a, b);
}

int f(int a, int b) {
    return a + b;
}

template<decltype(f)>        // alternative syntax
void apply2(int a, int b) {
    return g(a, b);
}

int main() {
    apply1<f>(2, 3); // return 5
    apply2<f>(2, 3); // return 5
}
```
